In a linear differential equation all terms involving the unknown fu are linear in the unknown functions or their derivatives. Linear here mea the unknown function or a derivative of it is multiplied by a number or a function. All other differential equations are non-linear. The easiest way an equation is nonlinear is to spot nonlinear terms where the unknown fu or their derivatives are multiplied by each other. For example, in

$$u'(t) = -a(t)u(t) + b(t)$$

the terms involving the unknown function u are linear: u' contains the de of the unknown function multiplied by unity, and au contains the u function multiplied by a known function. However,

$$u'(t) = u(t)(1 - u(t)),$$

is nonlinear because of the term $-u^2$ where the unknown function is mu by itself. Also

$$\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} = 0$$

is nonlinear because of the term uu_x where the unknown function app a product with itself or one if its derivatives. Another example of a ne equation is

$$u'' + \sin(u) = 0.$$

because $\sin(u)$ contains products of u,

$$\sin(u) = u - \frac{1}{3}u^3 + \dots$$

A series of forthcoming examples will explain who to tackle nonlinea ential equations with various techniques.

1 Basic examples using the logistic equatic

Consider the (scaled) logistic equation

$$u'(t) = u(t)(1 - u(t)).$$

This is a nonlinear differential equation which will be solved by different st in the following. A time discretization of (1) will either lead to a linear a equation or a nonlinear algebraic equation at each time level. In the case, the time discretization method transforms the nonlinear ODE int subproblems at each time level, and the solution is straightforward However, when the time discretization leads to nonlinear algebraic equat cannot (except in very rare cases) solve these without turning to approiterative solution methods

.1 Linearization by explicit time discretization

Forward Euler method to solve (1) results in

$$\frac{u^{n+1}-u^n}{\Delta t} = u^n(1-u^n),$$

hich is a *linear* algebraic equation for the unknown value u^{n+1} . Therefore, the onlinearity in the original equation poses no difficulty in the discrete algebraic quation. Any other explicit scheme in time will also give only linear algebraic quations to solve. For example, a typical 2nd-order Runge-Kutta method for .) reads,

$$u^* = u^n + \Delta t u^n (1 - u^n),$$

$$u^{n+1} = u^n + \Delta t \frac{1}{2} \left(u^n (1 - u^n) + u^* (1 - u^*) \right)$$

he first step is linear in the unknown u^* . Then u^* is computed and known in 1e next step, which is linear in the unknown u^{n+1} .

.2 Exact solution of nonlinear equations

witching to a Backward Euler scheme for (1),

$$\frac{u^n - u^{n-1}}{\Delta t} = u^n (1 - u^n), \tag{2}$$

sults in a nonlinear algebraic equation for the unknown value u^n . The equation of quadratic type:

$$\Delta t(u^{n})^{2} + (1 - \Delta t)u^{n} - u^{n-1} = 0.$$

/e shall now introduce a shorter and often cleaner notation for nonlinear lgebraic equation that appear at a given time level. The notation gets rid f the superscript that indicates the time level and is motivated by how we ill program the solution method for the algebraic equation, especially in more dvanced partial differential equation problems. The unknown in the algebraic quation is denoted by u, while u_1 is the value of the unknown at the previous me level (in general u_{ℓ} is the value of the unknown ℓ levels back in time). The uadratic equation for the unknown u^n in (2) can then be written

$$F(u) = \Delta t u^{2} + (1 - \Delta t)u - u_{1} = 0, \qquad (3)$$

nd the solution is

$$u = \frac{1}{2\Delta t} \left(-1 - \Delta t \pm \sqrt{(1 - \Delta t)^2 - 4\Delta t u_1} \right). \tag{4}$$

ere we encounter a fundamental challenge with nonlinear algebraic equations: ne equation may have more than one solution. How do we pick the right solution? In the present simple case we can expand the square root in in Δt and truncate after the linear term since the Backward Euler sche introduce an error proportional to Δt anyway. Using sympy we find the for Taylor series expansions of the roots:

```
>>> import sympy as sp
>>> dt, u_1, u = sp.symbols('dt u_1 u')
>>> r1, r2 = sp.solve(dt*u**2 + (1-dt)*u - u_1, u) # find roots
>>> r1
(dt - sqrt(dt**2 + 4*dt*u_1 - 2*dt + 1) - 1)/(2*dt)
>>> r2
(dt + sqrt(dt**2 + 4*dt*u_1 - 2*dt + 1) - 1)/(2*dt)
>>> print r1.series(dt, 0, 2)
-1/dt + 1 - u_1 + dt*(u_1**2 - u_1) + 0(dt**2)
>>> print r2.series(dt, 0, 2)
u_1 + dt*(-u_1**2 + u_1) + 0(dt**2)
```

We see that the r1 root, corresponding to a minus sign in front of the root in (4), behaves as $1/\Delta t$ and will therefore blow up as $\Delta t \rightarrow 0$! Only root is of relevance in this case.

1.3 Linearization

When the time integration of an ODE results in a nonlinear algebraic e we must normally find its solution by defining a sequence of linear eq and hope that the solutions of these linear equations converge to the solution of the nonlinear algebraic equation. Usually this means solv linear equation repeatedly in an iterative fashion. Sometimes the no equation is just approximated by a linear equation and no iteration is out.

Constructing a linear equation from a nonlinear one requires *linea* of each nonlinear term. This can be done manually as in Picard itera fully algorithmically as in Newton's method. Examples will best illustr to linearize nonlinear problems.

1.4 Picard iteration

Let us write (3) in a more compact form

$$F(u) = au^2 + bu + c = 0,$$

with $a = \Delta t$, $b = 1 - \Delta t$, and $c = -u_1$. Let u_- an available approximatic unknown u. Then we can linearize the term u^2 by writing u_-u . The r equation, $\hat{F}(u) = 0$, is linear and hence easy to solve:

$$F(u) \approx \tilde{F}(u) = au_{-}u + bu + c = 0$$

Since the equation $\hat{F} = 0$ is only approximate, the solution u does not exact solution u_e of the exact equation $F(u_e) = 0$, but we can hope t

.oser to u_e than u_- is, and hence it makes sense to repeat the procedure, i.e., et $u_- = u$ and solve $\hat{F}(u) = 0$ again.

The idea of turning a nonlinear equation into a linear one by using an pproximation u_{-} of u in nonlinear terms is a widely used approach that goes nder many names: *fixed-point iteration*, the method of *successive substitutions*, *onlinear Richardson iteration*, and *Picard iteration*. We will stick to the latter ame.

Picard iteration for solving the nonlinear equation arising from the Backward uler discretization of the logistic equation can be written as

$$u = -\frac{c}{au_- + b}, \quad u_- \leftarrow u \,.$$

he iteration is started with the value of the unknown at the previous time level: $_{-} = u_1$.

Some prefer an explicit iteration counter as superscript in the mathematical otation. Let u^k be the computed approximation to the solution in iteration k. 1 iteration k + 1 we want to solve

$$au^{k}u^{k+1} + bu^{k+1} + c = 0 \quad \Rightarrow \quad u^{k+1} = -\frac{c}{au^{k} + b}, \quad k = 0, 1, \dots$$

lowever, we will normally apply a mathematical notation in our final formulas nat is as close as possible to what we aim to write in a computer code and then e want to omit the k superscript in u.

topping criteria. The iteration method can typically be terminated when is change in the solution is smaller than a tolerance ϵ_u :

$$|u - u_-| \le \epsilon_u$$

r when the residual in the equation is sufficiently small (ϵ_r) ,

$$|F(u)| = |au^2 + bu + c| < \epsilon_r$$

/ith $\epsilon_r = 10^{-7}$ we seldom need more than about 5 iterations when solving this <code>vgistic</code> equation.

. single Picard iteration. Instead of iterating until a stopping criterion is ilfilled, one may iterate a specific number of times. Just one Picard iteration is opular as this corresponds to the intuitive idea of approximating a nonlinear erm like $(u^n)^2$ by $u^{n-1}u^n$. That is, one just applies a known value for the nknown at the previous time level in nonlinear terms. The corresponding time iscretization reads

$$\frac{u^n - u^{n-1}}{\Delta t} = u^n (1 - u^{n-1}).$$
(5)

This is obviously an approximation and does not correspond to a "pure difference method where the equation is sampled at a point and der replaced by differences. The best interpretation of the scheme (5) is a Ba Euler difference combined with a single Picard iteration at each time leve the value at the previous time level as start for the Picard iteration.

1.5 Linearization by a geometric mean

We consider now a Crank-Nicolson discretization of (1). This means t time derivative is approximated by a centered difference,

$$[D_t u = u(1-u)]^{n+\frac{1}{2}}$$

written out as

$$\frac{u^{n+1} - u^n}{\Delta t} = u^{n+\frac{1}{2}} - (u^{n+\frac{1}{2}})^2.$$

The term $u^{n+\frac{1}{2}}$ is normally approximated by an arithmetic mean,

$$u^{n+\frac{1}{2}} \approx \frac{1}{2}(u^n + u^{n+1})$$

such that the scheme involves the unknown function only at the time level we actually compute it. The same arithmetic mean applied to the ne term gives

$$(u^{n+\frac{1}{2}})^2 \approx \frac{1}{4}(u^n + u^{n+1})^2,$$

which is nonlinear in the unknown u^{n+1} . However, using a geometric n $(u^{n+\frac{1}{2}})^2$ is a way of linearizing the nonlinear term in (6):

$$(u^{n+\frac{1}{2}})^2 \approx u^n u^{n+1}$$
.

The linearized scheme for u^{n+1} now reads

$$\frac{u^{n+1} - u^n}{\Delta t} = \frac{1}{2}(u^n + u^{n+1}) + u^n u^{n+1},$$

which can readily be solved:

$$u^{n+1} = \frac{1 + \frac{1}{2}\Delta t}{1 + \Delta t u^n - \frac{1}{2}\Delta t} u^n$$

This scheme can be coded directly, and since there is no nonlinear a equation to solve by methods for those kind of problems we skip the sin notation (u for u^{n+1} and u_1 for u^n).

The geometric mean approximation is often very effective to de quadratic nonlinearities. Both the arithmetic and geometric mean app tions have truncation errors of order Δt^2 and are therefore compatil he truncation error of the centered difference approximation for U^\prime in the rank-Nicolson method.

Applying the operator notation for the means, the linearized Crank-Nicolson cheme for the logistic equation can be compactly expressed as

$$[D_t u = \overline{u}^t + \overline{u^2}^{t,g}]^{n+\frac{1}{2}}$$

temark. If we use an arithmetic instead of a geometric mean for the nonlinear rrm in (6), we end up with a nonlinear term $(u^{n+1})^2$. The term can be linearized s $u^n u^{n+1}$ in a Picard iteration approach. Observe that the geometric mean voids any iteration.

.6 Newton's method

he Backward Euler scheme (2) for the logistic equation leads to a nonlinear lgebraic equation (3). Now we write any nonlinear algebraic equation in the eneral and compact form

F(u) = 0.

ewton's method linearizes this equation by approximating F(u) by its Taylor ries expansion around a computed value u_{-} and keeping only the linear part:

$$F(u) = F(u_{-}) + F'(u_{-})(u - u_{-}) + \frac{1}{2}F''(u_{-})(u - u_{-})^{2} + \cdots$$
$$\approx F(u_{-}) + F'(u_{-})(u - u_{-}) = \hat{F}(u).$$

he linear equation $\hat{F}(u) = 0$ has the solution

$$u = u_{-} - \frac{F(u_{-})}{F'(u_{-})}$$

xpressed with an iteration index on the unknown, Newton's method takes on ne more familiar mathematical form

$$u^{k+1} = u^k - \frac{F(u^k)}{F'(u^k)}, \quad k = 0, 1, \dots$$

Application of Newton's method to the logistic equation discretized by the ackward Euler method is straightforward as we have

$$F(u) = au^2 + bu + c$$
, $a = \Delta t$, $b = 1 - \Delta t$, $c = -u_1$,

nd then

$$F'(u) = 2au + b$$

he iteration method becomes

 $u = u_{-} + \frac{au_{-}^2 + bu_{-} + c}{2au_{-} + b}, \quad u_{-} \leftarrow u.$

At each time level, we start the iteration by setting $u_{-} = u_1$. Stopping as listed for the Picard iteration can be used also for Newton's method

An alternative mathematical form, where we write out a, b, and c, at time level counter n and an iteration counter k, takes the form

$$u^{n,k+1} = u^{n,k} + \frac{\Delta t (u^{n,k})^2 + (1 - \Delta t) u^{n,k} - u^{n-1}}{2\Delta t u^{n,k} + 1 - \Delta t}, \quad u^{n,0} = u^{n-1}, \quad k = 0, \quad$$

The implementation is much closer to (7) than to (8), but the latter i aligned with the established mathematical notation used in the literatu

1.7 Relaxation

One iteration in Newton's method or Picard iteration consists of solving problem $\hat{F}(u) = 0$. Sometimes convergence problems arise because a solution u of $\hat{F}(u) = 0$ is "too far away" from the previously computed u_- . A remedy is to introduce a relaxation, meaning that we first solve $\hat{F}(u)$ for a suggested value u^* and then we take u as a weighted mean of what u_- , and what our linearized equation $\hat{F} = 0$ suggests, u^* :

$$u = \omega u^* + (1 - \omega)u_-$$

The parameter ω is known as a *relaxation parameter*, and a choice ω < prevent divergent iterations.

Relaxation in Newton's method can be directly incorporated in the iteration formula:

$$u = u_- - \omega \frac{F(u_-)}{F'(u_-)}$$

1.8 Implementation and experiments

The program $logistic.py^1$ contains implementations of all the meth scribed above. Below is an extract of the file showing how the Picard and methods are implemented for a Backward Euler discretization of the equation.

```
def BE_logistic(u0, dt, Nt, choice='Picard', eps_r=1E-3, omega=1)
    u = np.zeros(Nt+1)
    u[0] = u0
    for n in range(1, Nt+1):
        a = dt; b = 1 - dt; c = -u[n-1]
        if choice == 'Picard':
```

¹http://tinyurl.com/jvzzcfn/nonlin/logistic.py

```
def F(u):
            return a*u**2 + b*u + c
        u = u[n-1]
        k = 0
        while abs(F(u)) > eps r:
             u_{-} = omega*(-c/(a*u_{-} + b)) + (1-omega)*u_{-}
             k += 1
        u[n] = u_{-}
    elif choice == 'Newton':
        def F(u):
            return a*u**2 + b*u + c
        def dF(u):
            return 2*a*u + b
        u_{-} = u[n-1]
        k = 0
        while abs(F(u_)) > eps_r:
            u_{-} = u_{-} - F(u_{-})/dF(u_{-})
            k += 1
        u[n] = u
return u
```

The Crank-Nicolson method utilizing a linearization based on the geometric lean gives a simpler algorithm:

```
lef CN_logistic(u0, dt, N):
    u = np.zeros(N+1)
    u[0] = u0
    for n in range(0,N):
        u[n+1] = (1 + 0.5*dt)/(1 + dt*u[n] - 0.5*dt)*u[n]
    return u
```

Experiments with this program reveal the relative performance of the methods s summarized in the table below. The Picard and Newton columns reflect the pical number of iterations with these methods before the curve starts to flatten ut and the number of iterations is significantly reduced since the solution of the onlinear algebraic equation is very close to the starting value for the iterations he solution at the previous time level). Increasing Δt moves the starting value urther away from the solution of the nonlinear equation and one expects an icrease in the number of iterations. Picard iteration is very much more sensitive τ the size of Δt than Newton's method. The tolerance ϵ_r in residual-based copping criterion takes on a low and high value in the experiments.

Δt	ϵ_r	Picard	Newton
0.2	10^{-7}	5	2
0.2	10^{-3}	2	1
0.4	10^{-7}	12	3
0.4	10^{-3}	4	2
0.8	10^{-7}	58	3
0.8	10^{-3}	4	2

Remark. The simple Crank-Nicolson method with a geometric mean quadratic nonlinearity gives visually more accurate solutions than the Ba Euler discretization. Even with a tolerance of $\epsilon_r = 10^{-3}$, all the meth treating the nonlinearities in the Backward Euler discretization gives grap cannot be distinguished. So for accuracy in this problem, the time discret is much more crucial than ϵ_r . Ideally, one should estimate the error in t discretization, as the solution progresses, and set ϵ_r accordingly.

1.9 Generalization to a general nonlinear ODE

Let us see how the various methods in the previous sections can be ap the more generic model

$$u' = f(u, t),$$

where f is a nonlinear function of u.

Explicit time discretization. Explicit ODE methods like the Forwar scheme, Runge-Kutta methods, Adams-Bashforth methods all evaluatime levels where u is already computed, so nonlinearities in f do not p difficulties.

Backward Euler discretization. Approximating u' by a backward di leads to a Backward Euler scheme, which can be written as

$$F(u^{n}) = u^{n} - \Delta t f(u^{n}, t_{n}) - u^{n-1} = 0,$$

or alternatively

$$F(u) = u - \Delta t f(u, t_n) - u_1 = 0.$$

A simple Picard iteration, not knowing anything about the nonlinear st of f, must approximate $f(u, t_n)$ by $f(u_-, t_n)$:

$$\hat{F}(u) = u - \Delta t f(u_-, t_n) - u_1.$$

The iteration starts with $u_{-} = u_1$ and proceeds with repeating

$$u^* = \Delta t f(u_-, t_n) + u_1, \quad u = \omega u^* + (1 - \omega)u_-, \quad u_- \leftarrow u_2$$

until a stopping criterion is fulfilled.

Newton's method requires the computation of the derivative

$$F'(u) = 1 - \Delta t \frac{\partial f}{\partial u}(u, t_n)$$

Starting with the solution at the previous time level, $u_{-} = u_1$, we can the standard formula

12

$$u = u_{-} - \omega \frac{F(u_{-})}{F'(u_{-})} = u_{-}\omega \frac{u_{1} + \Delta t f(u, t_{n})}{1 - \Delta t \frac{\partial}{\partial u} f(u, t_{n})}$$

The geometric mean trick cannot be used unless we know that f has a special ructure with quadratic expressions in u.

'rank-Nicolson discretization. The standard Crank-Nicolson scheme with rithmetic mean approximation of f takes the form

$$\frac{u^{n+1} - u^n}{\Delta t} = \frac{1}{2} (f(u^{n+1}, t_{n+1}) + f(u^n, t_n)).$$

it roducing u for the unknown u^{n+1} and u_1 for u^n , we can write the scheme as nonlinear algebraic equation

$$F(u) = u - u_1 - \Delta t \frac{1}{2} f(u, t_{n+1}) - \Delta t \frac{1}{2} f(u_1, t_n) = 0$$

Picard iteration scheme must in general employ the linearization,

$$\hat{F}(u) = u - u_1 - \Delta t \frac{1}{2} f(u_-, t_{n+1}) - \Delta t \frac{1}{2} f(u_1, t_n),$$

hile Newton's method can apply the general formula, but we need to derive

$$F'(u) = 1 - \frac{1}{2}\Delta t \frac{\partial f}{\partial u}(u, t_{n+1})$$

Systems of nonlinear algebraic equations

nplicit time discretization methods for a system of ODEs, or a PDE, lead to *ystems* of nonlinear algebraic equations, written compactly as

$$F(u) = 0,$$

here u is a vector of unknowns $u = (u_0, \ldots, u_N)$, and F is a vector function: ' = (F_0, \ldots, F_N) . Sometimes the equation system has a special structure ecause of the underlying problem, e.g.,

$$A(u)u = b(u),$$

ith A(u) as an $(N+1) \times (N+1)$ matrix function of u and b as a vector function: = (b_0, \ldots, b_N) .

We shall next explain how Picard iteration and Newton's method can be pplied to systems like F(u) = 0 and A(u)u = b(u). The exposition has a focus n ideas and practical computations. More theoretical considerations, including uite general results on convergence properties of these methods, can be found ι Kelley [1].

2.1 Picard iteration

We cannot apply Picard iteration to nonlinear equations unless there special structure. For the commonly arising case A(u)u = b(u) we can be the product A(u)u to $A(u_{-})u$ and b(u) as $b(u_{-})$. That is, we use the previously computed approximation in A and b to arrive at a *linear systu*:

$$A(u_{-})u = b(u_{-}).$$

A relaxed iteration takes the form

$$A(u_{-})u^{*} = b(u_{-}), \quad u = \omega u^{*} + (1 - \omega)u_{-}.$$

In other words, we solve a system of nonlinear algebraic equations as a s of linear systems.

Algorithm for relaxed Picard iteration. Given A(u)u = b(u) and an initial guess u_- , iterate until convergence 1. solve $A(u_-)u^* = b(u_-)$ with respect to u^* 2. $u = \omega u^* + (1 - \omega)u_-$

3.
$$u_{-} \leftarrow u$$

2.2 Newton's method

The natural starting point for Newton's method is the general nonlinea equation F(u) = 0. As for a scalar equation, the idea is to approximate Fa known value u_{-} by a linear function \hat{F} , calculated from the first two t a Taylor expansion of F. In the multi-variate case these two terms become

$$F(u_{-}) + J(u_{-}) \cdot (u - u_{-}),$$

where J is the *Jacobian* of F, defined by

$$I_{i,j} = \frac{\partial F_i}{\partial u_j}$$

So, the original nonlinear system is approximated by

$$\hat{F}(u) = F(u_{-}) + J(u_{-}) \cdot (u - u_{-}) = 0$$

which is linear in u and can be solved in a two-step procedure: fir $J\delta u = -F(u_{-})$ with respect to the vector δu and then update $u = u_{-}$ relaxation parameter can easily be incorporated:

$$u = \omega(u_- + \delta u) + (1 - \omega)u_- = \omega_- + \omega \delta u.$$

Algorithm for Newton's method.

Given F(u) = 0 and an initial guess u_{-} , iterate until convergence:

1. solve
$$J\delta u = -F(u_{-})$$
 with respect to δu
2. $u = u_{-} + \omega)\delta u$
3. $u_{-} \leftarrow u$

For the special system with structure A(u)u = b(u),

$$F_i = \sum_k A_{i,k}(u)u_k - b_i(u)$$

 nd

$$J_{i,j} = \sum_{k} \frac{\partial A_{i,k}}{\partial u_j} u_k + A_{i,j} - \frac{\partial b_i}{\partial u_j}.$$
 (10)

/e realize that the Jacobian needed in Newton's method consists of $A(u_{-})$ as i the Picard iteration plus two additional terms arising from the differentiation. sing the notation A'(u) for $\partial A/\partial u$ (a quantity with three indices: $\partial A_{i,k}/\partial u_j$), nd b'(u) for $\partial b/\partial u$ (a quantity with two indices: $\partial b_i/\partial u_j$), we can write the near system to be solved as

$$(A + A'u + b')\delta u = -Au + b,$$

r

$$(A(u_{-}) + A'(u_{-})u_{-} + b'(u_{i}))\delta u = -A(u_{-})u_{-} + b(u_{-})$$

earranging the terms demonstrates the difference from the system solved in ach Picard iteration:

$$\underbrace{A(u_-)(u_- + \delta u) - b(u_-)}_{\text{Picard system}} + \gamma(A'(u_-)u_- + b'(u_i))\delta u = 0.$$

lere we have inserted a parameter γ such that $\gamma = 0$ gives the Picard system nd $\gamma = 1$ gives the Newton system. Such a parameter can be handy in software) easily switch between the methods.

.3 Stopping criteria

et $||\cdot||$ be the standard Eucledian vector norm. Four termination criteria are such in use:

• Absolute change in solution: $||u - u_-|| \le \epsilon_u$

- Absolute residual: $||F(u)|| \le \epsilon_r$
- Relative residual: $||F(u)|| \le \epsilon_r ||F(u_0)||$

To prevent divergent iterations to run forever, one terminates the ite when the current number of iterations k exceeds a maximum value k_{ma}

The relative criteria are most used since they are not sensitive to t acteristic size of u. Nevertheless, the relative criteria can be misleadir, the initial start value for the iteration is very close to the solution, s unnecessary reduction in the error measure is enforced. In such cases the a criteria work better. It is common to combine the absolute and relative n of the size of the residual, as in

$$||F(u)|| \le \epsilon_{rr} ||F(u_0)|| + \epsilon_{ra}$$

where ϵ_{rr} is the tolerance in the relative criterion and ϵ_{ra} is the tolerance absolute criterion. With a very good initial guess for the iteration (typic solution of a differential equation at the previous time level), the term | is small and ϵ_{ra} is the dominating tolerance. Otherwise, $\epsilon_{rr}||F(u_0)||$ relative criterion dominates.

With the change in solution as criterion we can formulate and cc absolute and relative measure of the change in the solution:

$$||\delta u|| \le \epsilon_{ur} ||u_0|| + \epsilon_{ua}$$

The ultimate termination criterion, combining the residual and the in solution tests with a test on the maximum number of iterations allow expressed as

$$||F(u)|| \le \epsilon_{rr} ||F(u_0)|| + \epsilon_{ra} \text{ or } ||\delta u|| \le \epsilon_{ur} ||u_0|| + \epsilon_{ua} \text{ or } k > k_{\max}.$$

2.4 Example: A nonlinear ODE model from epidem

The simplest model spreading of a disease, such as a flu, takes the fo $2\times 2~{\rm ODE}$ system

$$S' = -\beta SI,$$

$$I' = \beta SI - \nu I$$

where S(t) is the number of people who can get ill (susceptibles) and I(number of people who are ill (infected). The constants $\beta > 0$ and $\nu > 0$ given along with initial conditions S(0) and I(0).

mplicit time discretization. A Crank-Nicolson scheme leads to a 2×2 /stem of nonlinear algebraic equations in the unknowns S^{n+1} and I^{n+1} :

$$\frac{S^{n+1} - S^n}{\Delta t} = -\beta [SI]^{n+\frac{1}{2}} \approx -\frac{\beta}{2} (S^n I^n + S^{n+1} I^{n+1}), \tag{16}$$
$$\frac{I^{n+1} - I^n}{\Delta t} = \beta [SI]^{n+\frac{1}{2}} - \nu I^{n+\frac{1}{2}} \approx \frac{\beta}{2} (S^n I^n + S^{n+1} I^{n+1}) - \frac{\nu}{2} (I^n + I^{n+1}). \tag{17}$$

stroducing S for S^{n+1} , S_1 for S^n , I for I^{n+1} , I_1 for I^n , we can rewrite the /stem as

$$F_S(S,I) = S - S_1 + \frac{1}{2}\Delta t\beta(S_1I_1 + SI) = 0,$$
(18)

$$F_I(S,I) = I - I_1 - \frac{1}{2}\Delta t\beta(S_1I_1 + SI) - \frac{1}{2}\Delta t\nu(I_1 + I) = 0.$$
(19)

Picard iteration. We assume that we have approximations S_{-} and I_{-} to and I. A way of linearizing the only nonlinear term SI is to write $I_{-}S$ in ne $F_{S} = 0$ equation and $S_{-}I$ in the $F_{I} = 0$ equation, which also decouples the quations. Solving the resulting linear equations with respect to the unknowns and I gives

$$S = \frac{S_1 - \frac{1}{2}\Delta t\beta S_1 I_1}{1 + \frac{1}{2}\Delta t\beta I_-},$$
$$I = \frac{I_1 + \frac{1}{2}\Delta t\beta S_1 I_1}{1 - \frac{1}{2}\Delta t\beta S_- + \nu}.$$

he solutions S and I are stored in S_- and I_- and a new iteration is carried ut.

lewton's method. The nonlinear system (18)-(19) can be written as F(u) = with $F = (F_S, F_I)$ and u = (S, I). The Jacobian becomes

$$J = \begin{pmatrix} \frac{\partial}{\partial S} F_S & \frac{\partial}{\partial I} F_S \\ \frac{\partial}{\partial S} F_I & \frac{\partial}{\partial I} F_I \end{pmatrix} = \begin{pmatrix} 1 + \frac{1}{2} \Delta t \beta I & \frac{1}{2} \Delta t \beta \\ -\frac{1}{2} \Delta t \beta S & 1 - \frac{1}{2} \Delta t \beta I - \frac{1}{2} \Delta t \nu \end{pmatrix}.$$

he Newton system to be solved in each iteration is then

$$\begin{pmatrix} 1+\frac{1}{2}\Delta t\beta I_{-} & \frac{1}{2}\Delta t\beta S_{-} \\ -\frac{1}{2}\Delta t\beta S_{-} & 1-\frac{1}{2}\Delta t\beta I_{-} - \frac{1}{2}\Delta t\nu \end{pmatrix} \begin{pmatrix} \delta S \\ \delta I \end{pmatrix} = \\ \begin{pmatrix} S_{-} - S_{1} + \frac{1}{2}\Delta t\beta (S_{1}I_{1} + S_{-}I_{-}) \\ I_{-} - I_{1} - \frac{1}{2}\Delta t\beta (S_{1}I_{1} + S_{-}I_{-}) - \frac{1}{2}\Delta t\nu (I_{1} + I_{-}) \end{pmatrix}$$

Remark. For this particular system explicit time integration methovery well. The 4-th order Runge-Kutta method is an excellent balance high accuracy, high efficiency, and simplicity.

3 Linearization at the differential equation

The attention is now turned to nonlinear partial differential equations and application of the techniques explained for ODEs. The model prob nonlinear diffusion equation

$$\begin{aligned} \frac{\partial u}{\partial t} &= \nabla \cdot (\alpha(u)\nabla u) + f(u), \qquad & \boldsymbol{x} \in \Omega, \ t \in (0,T], \\ -\alpha(u)\frac{\partial u}{\partial n} &= g, \qquad & \boldsymbol{x} \in \partial\Omega_N, \ t \in (0,T], \\ u &= u_0, \qquad & \boldsymbol{x} \in \partial\Omega_D, \ t \in (0,T]. \end{aligned}$$

Our aim is to discretize the problem in time and then present tec for linearizing the time-discrete PDE problem "at the PDE level" su we transform the nonlinear stationary PDE problems at each time level sequence of linear PDE problems, which can be solved using any met linear PDEs. This strategy avoids the solution systems of nonlinear a equations. In Section 4 we shall take the opposite (and more common) ap discretize the nonlinear problem in time and space first, and then so resulting nonlinear algebraic equations at each time level by the met Section 2.

3.1 Explicit time integration

The nonlinearities in the PDE are trivial to deal with if we choose an time integration method for (20), such as the Forward Euler method:

$$D_t^+ u = \nabla \cdot (\alpha(u)\nabla u) + f(u)]^n$$

which leads to a linear equation in the unknown u^{n+1} :

$$\frac{u^{n+1}-u^n}{\Delta t} = \nabla \cdot \left(\alpha(u^n)\nabla u^n\right) + f(u^n)\,.$$

3.2 Picard iteration

A Backward Euler scheme for (20) reads

$$D_t^- u = \nabla \cdot (\alpha(u)\nabla u) + f(u)]^n$$
.

Written out,

$$\frac{u^n - u^{n-1}}{\Delta t} = \nabla \cdot (\alpha(u^n)\nabla u^n) + f(u^n)$$
(23)

his is a nonlinear, stationary PDE for the unknown function $u^n(x)$. We itroduce a Picard iteration with k as iteration counter. A typical linearization f the $\nabla \cdot \alpha(u^n) \nabla u^n$ term in iteration k + 1 is to use the previously computed n,k approximation in the diffusion coefficient: $\alpha(u^{n,k})$. The nonlinear source erm is treated similarly: $f(u^{n,k})$. The unknown function $u^{n,k+1}$ then fulfills the near PDE

$$\frac{u^{n,k+1} - u^{n-1}}{\Delta t} = \nabla \cdot (\alpha(u^{n,k})\nabla u^{n,k+1}) + f(u^{n,k}).$$
(24)

he initial guess for the Picard iteration at this time level can be taken as the plution at the previous time level: $u^{n,0} = u^{n-1}$.

We can alternatively apply the notation where u corresponds to the unknown e want to solve for, i.e., $u^{n,k+1}$ above, let u_{-} be the most recently computed alue, $u^{n,k}$ above, and let u_1 denote the unknown function at the previous time evel, u^{n-1} above. The PDE to be solved in a Picard iteration then looks like

$$\frac{u-u_1}{\Delta t} = \nabla \cdot \left(\alpha(u_-)\nabla u\right) + f(u_-) \,. \tag{25}$$

t the beginning of the iteration we start with the value from the previous time wel: $u_{-} = u_{1}$.

.3 Newton's method

t time level n we have to solve the stationary PDE (23), this time with Newton's lethod. Normally, Newton's method is defined for systems of *algebraic equations*, ut the idea of the method can be applied at the PDE level too.

Let $u^{n,k}$ be an approximation to u^n . We seek a better approximation on the rm

$$u^n = u^{n,k} + \delta u \,. \tag{26}$$

he idea is to insert (26) in (23), Taylor expand the nonlinearities and only eep the terms that are linear in δu . Then we can solve a linear PDE for the prection δu and use (26) to find a new approximation $u^{n,k+1} = u^{n,k} + \delta u$ to ⁿ.

Inserting (26) in (23) gives

$$\frac{u^{n,k} + \delta u - u^{n-1}}{\Delta t} = \nabla \cdot \left(\alpha (u^{n,k} + \delta u) \nabla (u^{n,k} + \delta u)\right) + f(u^{n,k} + \delta u) \qquad (27)$$

le can Taylor expand $\alpha(u^{n,k} + \delta u)$ and $f(u^{n,k} + \delta u)$:

Inserting the linear approximations of α and f in (27) results in

$$\begin{aligned} \frac{u^{n,k} + \delta u - u^{n-1}}{\Delta t} &= \nabla \cdot (\alpha(u^{n,k}) \nabla u^{n,k}) + f(u^{m,k}) + \\ & \nabla \cdot (\alpha(u^{n,k}) \nabla \delta u) + \nabla \cdot (\alpha'(u^{n,k}) \delta u \nabla u^{n,k}) + \\ & \nabla \cdot (\alpha'(u^{n,k}) \delta u \nabla \delta u) + f'(u^{n,k}) \delta u \end{aligned}$$

The term $\alpha'(u^{n,k})\delta u\nabla \delta u$ is $\mathcal{O}(\delta u^2)$ and therefore omitted. Reorganiz equation gives a PDE for δu that we can write in short form as

$$\delta F(\delta u; u^{n,k}) = -F(u^{n,k}),$$

where

$$F(u^{n,k}) = \frac{u^{n,k} - u^{n-1}}{\Delta t} - \nabla \cdot (\alpha(u^{n,k})\nabla u^{n,k}) + f(u^{n,k}),$$

$$\delta F(\delta u; u^{n,k}) = -\frac{1}{\Delta t}\delta u + \nabla \cdot (\alpha(u^{n,k})\nabla \delta u) + \nabla \cdot (\alpha'(u^{n,k})\delta u\nabla u^{n,k}) + f'(u^{n,k})\delta u.$$

Note that δF is a linear function of δu , and F contains only terms t known, such that the PDE for δu is indeed linear.

The form $\delta F = -F$ resembles the Newton system $J\delta u = -F$ for systalgebraic equations, with δF as $J\delta u$. The unknown vector in a linear sy algebraic equations enters the system as a matrix-vector product $(J\delta u)$, the PDE level we have a linear differential operator instead (δF) .

We can rewrite the PDE for δu in a slightly different way too if w $u^{n,k} + \delta u$ as $u^{n,k+1}$.

$$\frac{u^{n,k+1} - u^{n-1}}{\Delta t} = \nabla \cdot (\alpha(u^{n,k})\nabla u^{n,k+1}) + f(u^{n,k}) + \nabla \cdot (\alpha'(u^{n,k})\delta u\nabla u^{n,k}) + f'(u^{n,k})\delta u.$$

Note that the first line is the same PDE as arise in the Picard iteration, w remaining terms arise from the differentiations that are an inherent ing in Newton's method.

For coding we want to introduce u_{-} for $u^{n,k}$ and u_{1} for u^{n-1} . The f for F and δF are then

$$F(u_{-}) = \frac{u_{-} - u_{1}}{\Delta t} - \nabla \cdot (\alpha(u_{-})\nabla u_{-}) + f(u_{-}), \qquad (32)$$

$$\delta F(\delta u; u_{-}) = -\frac{1}{\Delta t} \delta u + \nabla \cdot (\alpha(u_{-})\nabla \delta u) +$$

 $\nabla \cdot (\alpha'(u_{-})\delta u \nabla u_{-}) + f'(u_{-})\delta u.$ (33)

he form that orders the PDE as the Picard iteration terms plus the Newton iethod's derivative terms becomes

$$\frac{u-u_1}{\Delta t} = \nabla \cdot (\alpha(u_-)\nabla u) + f(u_-) + \nabla \cdot (\alpha'(u_-)\delta u\nabla u_-) + f'(u_-)\delta u.$$
(34)

Discretization of nonlinear differential equations

ection 3 presents methods for linearizing time-discrete PDEs directly prior to iscretization in space. We can alternatively carry out the discretization in space nd of the time-discrete nonlinear PDE problem and get a system of nonlinear lgebraic equations, which can be solved by Picard iteration or Newton's method s presented in Section 2. This latter approach will now be described in detail.

We shall work with the 1D problem

$$-(\alpha(u)u')' + au = f(u), \quad x \in (0,L), \quad \alpha(u(0))u'(0) = C, \ u(L) = 0.$$
(35)

his problem is of the same nature as those arising from implicit time integration f a nonlinear diffusion PDE as outlined in Section 3.2 (set $a = 1/\Delta t$ and let (u) incorporate the nonlinear source term as well as known terms with the me-dependent unknown function at the previous time level).

.1 Finite difference discretizations

Discretization. The nonlinearity in the differential equation (35) poses no more difficulty than a variable coefficient, as in $(\alpha(x)u')'$. We can therefore use standard approach to discretizing the Laplace term with a variable coefficient:

$$[-D_x \alpha D_x u + au = f]_i.$$

/riting this out for a uniform mesh with points $x_i = i\Delta x, i = 0, \dots, N_x$, leads

$$-\frac{1}{\Delta x^2} \left(\alpha_{i+\frac{1}{2}} (u_{i+1} - u_i) - \alpha_{i-\frac{1}{2}} (u_i - u_{i-1}) \right) + au_i = f(u_i) \,. \tag{36}$$

This equation is valid at all the mesh points $i = 0, 1, ..., N_x - 1$. At we have the Dirichlet condition $u_i = 0$. The only difference from the ca $(\alpha(x)u')'$ and f(x) is that now α and f are functions of u and not on $(\alpha(u(x))u')'$ and f(u(x)).

The quantity $\alpha_{i+\frac{1}{2}}$, evaluated between two mesh points, needs a construction α depends on u and u is only known at the mesh points, we need to $\alpha_{i+\frac{1}{2}}$ in terms of u_i and u_{i+1} . For this purpose we use an arithmetical through a harmonic mean is also common in this context if α feature jumps. There are two choices of arithmetic means:

$$\alpha_{i+\frac{1}{2}} \approx \alpha(\frac{1}{2}(u_i + u_{i+1}) = [\alpha(\overline{u}^x)]^{i+\frac{1}{2}},$$

$$\alpha_{i+\frac{1}{2}} \approx \frac{1}{2}(\alpha(u_i) + \alpha(u_{i+1})) = [\overline{\alpha(u)}^x]^{i+\frac{1}{2}}$$

Equation (36) with the latter approximation then looks like

$$-\frac{1}{2\Delta x^2} \left((\alpha(u_i) + \alpha(u_{i+1}))(u_{i+1} - u_i) - (\alpha(u_{i-1}) + \alpha(u_i))(u_i - u_i) + au_i = f(u_i), \right)$$

or written more compactly,

$$[-D_x\overline{\alpha}^x D_x u + au = f]_i.$$

At mesh point i = 0 we have the boundary condition $\alpha(u)u' = C$, v discretized by

$$[\alpha(u)D_{2x}u = C]_0,$$

meaning

$$\alpha(u_0)\frac{u_1-u_{-1}}{2\Delta x} = C\,.$$

The fictitious value u_{-1} can be eliminated with the aid of (39) for i = 0. F (39) should be solved with respect to u_{i-1} and that value (for i = 0) sh inserted in (40), but it is algebraically much easier to do it the other way Alternatively, one can use a ghost cell $[-\Delta x, 0]$ and update the u_{-1} , the ghost cell according to (40) after every Picard or Newton iteratio: an approach means that we use a known u_{-1} value in (39) from the p iteration.

Solution of algebraic equations. The nonlinear algebraic equation are of the form A(u)u = b(u) with

$$\begin{aligned} A_{i,i} &= \frac{1}{2\Delta x^2} (-\alpha(u_{i-1}) + 2\alpha(u_i) - \alpha(u_{i+1})) + a, \\ A_{i,i-1} &= -\frac{1}{2\Delta x^2} (\alpha(u_{i-1}) + \alpha(u_i)), \\ A_{i,i+1} &= -\frac{1}{2\Delta x^2} (\alpha(u_i) + \alpha(u_{i+1})), \\ b_i &= f(u_i) \,. \end{aligned}$$

he matrix A(u) is tridiagonal: $A_{i,j} = 0$ for j > 1+1 and j < i-1. The obvious icard iteration scheme is to use previously computed values of u_i in A(u) and (u), as described more in detail in Section 2.

Newton's method requires computation of the Jacobian. Here it means that e need to differentiate F(u) = A(u)u - b(u) with respect to $u_0, u_1, \ldots, u_{N_x-1}$. onlinear equation number *i* has the structure

$$\dot{i} = A_{i,i-1}(u_{i-1}, u_i)u_{i-1} + A_{i,i}(u_{i-1}, u_i, u_{i+1})u_i + A_{i,i+1}(u_i, u_{i+1})u_{i+1} - b_i(u_i).$$

he Jacobian becomes

$$\begin{split} J_{i,i} &= \frac{\partial F_i}{\partial u_i} = \frac{\partial A_{i,i-1}}{\partial u_i} u_{i-1} + \frac{\partial A_{i,i}}{\partial u_i} u_i - \frac{\partial b_i}{\partial u_i} + A_{i,i} + \frac{\partial A_{i,i+1}}{\partial u_i} u_{i+1} - \frac{\partial b_i}{\partial u_i} \\ &= \frac{1}{2\Delta x^2} (-\alpha'(u_i) u_{i-1} + 2\alpha'(u_i) u_i + (-\alpha(u_{i-1}) + 2\alpha(u_i) - \alpha(u_{i+1}))) + \\ &a - \frac{1}{2\Delta x^2} \alpha'(u_i) u_{i+1}) - b'(u_i), \end{split}$$

$$J_{i,i-1} &= \frac{\partial F_i}{\partial u_{i-1}} = \frac{\partial A_{i,i-1}}{\partial u_{i-1}} u_{i-1} + A_{i-1,i} + \frac{\partial A_{i,i}}{\partial u_{i-1}} u_i - \frac{\partial b_i}{\partial u_{i-1}} \\ &= \frac{1}{2\Delta x^2} (-\alpha'(u_{i-1}) u_{i-1} - (\alpha(u_{i-1}) + \alpha(u_i)) + \alpha'(u_{i-1}) u_i), \\ J_{i,i+1} &= \frac{\partial A_{i,i+1}}{\partial u_{i-1}} u_{i+1} + A_{i+1,i} + \frac{\partial A_{i,i}}{\partial u_{i+1}} u_i - \frac{\partial b_i}{\partial u_{i+1}} \\ &= \frac{1}{2\Delta x^2} (-\alpha'(u_{i+1}) u_{i+1} - (\alpha(u_i) + \alpha(u_{i+1})) + \alpha'(u_{i+1}) u_i) \,. \end{split}$$

he explicit expression for nonlinear equation number i, $F_i(u_0, u_1, \ldots)$, arises om moving all terms in (39) to the left-hand side. Then we have $J_{i,j}$ and F_i nodulo the boundary conditions) and can implement Newton's method.

We have seen, and can see from the present example, that the linear system 1 Newton's method contains all the terms present in the system that arises 1 the Picard iteration method. The extra terms in Newton's method can be 1 ultiplied by a factor such that it is easy to program one linear system and set 1 is factor to 0 or 1 to generate the Picard or Newton system.

4.2 Finite element discretizations

For the finite element discretization we first need to derive the var problem. Let V be an appropriate function space with basis functions { Because of the Dirichlet condition at x = L we require $\psi_i(L) = 0, i \in \mathcal{I}_s$ Galerkin's method, we multiply the differential equation by any $v \in$ integrate terms with second-order derivatives by parts:

$$\int_0^L \alpha(u)u'v'\,\mathrm{d}x + \int_0^L auv\,\mathrm{d}x = \int_0^L f(u)v\,\mathrm{d}x + [\alpha(u)u'v]_0^L, \quad \forall v \in \mathbb{C}$$

The Neumann condition at the boundary x = 0 is inserted in the bounda

$$[\alpha(u)u'v]_0^L = \alpha(u(L))u'(L)v(L) - \alpha(u(0))u'(0)v(0) = 0 - Cv(0) = -Cv(0) = -Cv(0)$$

The variational problem is then: find $u \in V$ such that

$$\int_0^L \alpha(u)u'v'\,\mathrm{d}x + \int_0^L auv\,\mathrm{d}x = \int_0^L f(u)v\,\mathrm{d}x - Cv(0), \quad \forall v \in V.$$

To derive the algebraic equations we also demand the above equations for $v = \psi_i$, $i \in \mathcal{I}_s$, and we set $u = \sum_{i \in \mathcal{I}_s} c_j \psi_j$. The result is

$$\sum_{j\in\mathcal{I}_s} \left(\int_0^L \alpha(\sum_{k\in\mathcal{I}_s} c_k \psi_k) \psi'_j \psi'_i \,\mathrm{d}x \right) c_j = \int_0^L f(\sum_{k\in\mathcal{I}_s} c_k \psi_k) \psi_i \,\mathrm{d}x - C\psi_i(0),$$

Remark. Fundamental integration problem Methods that use the Gal weighted residual principle face a fundamental difficulty in nonlinear problem how can we integrate a terms like $\int_0^L \alpha(\sum_k c_k \psi_k) \psi'_i \psi'_j dx$ and $\int_0^L f(\sum_k c_k \psi_k) \psi'_i \psi'_j dx$ and $\int_0^L f(\sum_k c_k \psi_k) \psi_i dx$ and for the α function can resort to numerical integration, provided an approximate $\sum_k c_k \psi_k$ used for the argument u in f and α . If we want to derive the structur nonlinear algebraic equations, we need to apply numerical integration b the nodes only and/or the group finite element method.

4.3 The group finite element method

Finite element notation. Let us simplify the model problem for a w set a = 0, $\alpha = 1$, $f(u) = u^2$, and have Dirichlet conditions at both en that we get a very simple nonlinear problem $-u'' = u^2$. The variational then

$$\int_0^L u'v' \, \mathrm{d}x = \int_0^L u^2 v \, \mathrm{d}x, \quad \forall v \in V.$$

he term with u'v' is well known so the only new feature is the term $\int u^2 v \, dx$.

Introduction of finite element basis functions φ_i means setting

$$\psi_i = \varphi_{\nu(i)}, \quad i \in \mathcal{I}_s$$

here degree of freedom number $\nu(j)$ in the mesh corresponds to unknown umber j. When the degrees of freedom are just the function values at nodes, e have that $c_j = u(x_{\nu(j)}) = u_{\nu(j)}$, i.e., the value of u at node number $\nu(j)$. The nite element expansion for u is now

$$u = \sum_{j \in I_b} U_j \varphi_j + \sum_{j \in \mathcal{I}_s} \varphi_{\nu(j)} u_{\nu(j)},$$

ith the U_j quantities being prescribed Dirichlet values at some nodes with umbers in the index I_b . Instead of the $\nu(j)$ indices in the sum $\sum_{j \in \mathcal{I}_s} \varphi_{\nu(j)} u_{\nu(j)}$, e just write $\sum_j \varphi_j u_j$. This is possible by saying that j runs over a transformed idex set: { $\nu(0), \nu(1), \ldots, \nu(N)$ }. In the following we drop the boundary term $\sum_j U_j \varphi_j$ and write $u = \sum_j \varphi_j u_j$. The replacement of c_j by u_j as explained is notivated by simpler interpretation of the nonlinear algebraic equations as a nite difference scheme.

ntegrating nonlinear functions. Consider the term $\int u^2 v \, dx$ in the variaonal formulation with $v = \varphi_i$ and $u = \sum_k \varphi_k u_k$:

$$\int_0^L (\sum_k u_k \varphi_k)^2 \varphi_i \, \mathrm{d}x \, .$$

valuating this integral for P1 elements (see Problem 9) results in the expression

$$\frac{h}{12}(u_{i-1}^2 + 2u_i(u_{i-1} + u_{i+1}) + 6u_i^2 + u_{i+1}^2),$$

) be compared with the simple value u_i^2 that would arise in a finite difference iscretization. More complicated f(u) functions give rise to much more lengthy spressions, if it is possible to carry out the integral symbolically.

inite element approximation of functions of u. Since we already expand as $\sum_{j} \varphi_{j} u_{j}$ we may use the same approximation for nonlinearities. That is, ny function can be expanded as a sum of basis functions times the function alues. In particular,

$$f(u) \approx \sum_{j \in I_b} \varphi_j f(u_j) + \sum_j \psi_j(x) f(u_j),$$

here the first sum contain f values at the boundary where u has Dirichlet onditions and the other sum is over the node values j where u is unknown. however, for f there is no reason two have two summations as we do not need o distinguish between the nodes where u are known or unknown. Therefore, we an collapse the two sums into one (over all nodes, $j = 0, \ldots, N_n$) and write

$$f(u) \approx \sum_{j=0}^{N_n} \varphi_j(x) f(u_j)$$

This approximation is known as the group finite element method or the approximation technique.

The principal advantage of the group finite element method is for ϵ the symbolic form of difference equations in nonlinear problems. The s form is useful for comparing finite element and finite difference equations linear differential equation problems. Computer programs will always in $\int f(u)\varphi_i dx$ numerically by using an existing approximation of u in f(t)that the integrand can be sampled at any spatial point.

Application. Let use the group finite element method to derive the t the difference equation corresponding to f(u) in the differential equation have

$$\int_0^L f(u)\varphi_i \,\mathrm{d}x \approx \int_0^L (\sum_j \varphi_j f(u_j))\varphi_i \,\mathrm{d}x = \sum_j \left(\int_0^L \varphi_i \varphi_j \,\mathrm{d}x\right) f(u_j)$$

We recognize this expression as the mass matrix M, arising from $\int dt$ times the vector $f = (f(u_0), f(u_1), \ldots,)$: Mf. The associated terms difference equations are

$$\frac{h}{6}(f(u_{i-1}) + 4f(u_i) + f(u_{i+1}))$$

Occasionally, we want to interpret this expression in terms of finite difficult and then a rewrite of this expression is convenient:

$$\frac{h}{6}(f(u_{i-1}) + 4f(u_i) + f(u_{i+1})) = h[f(u) - \frac{h^2}{6}D_x D_x f(u)]_i.$$

We may lump the mass matrix through integration with the Trapezoid In that case the f(u) term in the differential equation gives rise to a sing $hf(u_i)$, just as in the finite difference method.

4.4 Numerical integration of nonlinear terms

Let us reconsider a term $\int f(u)v \, dx$ as treated in the previous section now we want to integrate this term numerically. Such an approach can easy-to-interpret formulas if we apply a numerical integration rule that the integrand at the node points.

The term in question takes the form

$$\int_0^L f(\sum_k u_k \varphi_k) \varphi_i \,\mathrm{d}x$$

valuation of the integrand at a node x_ℓ leads to a collapse of the sum $\sum_k u_k \varphi_k$) one term because

$$\sum_{k} u_{k} \varphi_{k}(x_{\ell}) = u_{\ell} \,.$$
$$f(\sum_{k} u_{k} \underbrace{\varphi_{k}(x_{\ell})}_{\delta_{k\ell}}) \underbrace{\varphi_{i}(x_{\ell})}_{\delta_{i\ell}} = f(u_{\ell})\delta_{i\ell},$$

here we have used the Kronecker delta $\delta_{ij} = 0$ if $i \neq j$ and $\delta_{ij} = 1$ if i = j. Considering the Trapezoidal rule for integration, we have

$$\int_{0}^{L} f(\sum_{k} u_{k} \varphi_{k})(x) \varphi_{i}(x) \, \mathrm{d}x \approx h \sum_{\ell=0}^{N_{n}} f(u_{\ell}) \delta_{i\ell} - \mathcal{C} = h f(u_{i}) \, .$$

he term \mathcal{C} contains the evaluations of the integrand at the ends with weight $\frac{1}{2}$, eeded to make a true Trapezoidal rule. The answer $hf(u_i)$ must therefore be ultiplied by $\frac{1}{2}$ if i = 0 or $i = N_n$. $(\mathcal{C} = \frac{h}{2}f(u_0)\varphi_i(0) + \frac{h}{2}f(u_{N_n})\varphi_i(L).)$

One can easily use the Trapezoidal rule on the reference cell and assemble re contributions. It is a bit more work in this context, but working on the efference cell is safer as that approach is guaranteed to handle discontinuous erivatives of finite element functions correctly.

The conclusion is that it suffices to use the Trapezoidal rule if one wants) derive the difference equations in the finite element method and make them milar to those arising in the finite difference method. The Trapezoidal rule as sufficient accuracy for P1 elements, but for P2 elements one should turn to impson's rule.

.5 Finite element discretization of a variable coefficient Laplace term

urning back to the model problem (35), it remains to calculate the contribution f the $(\alpha u')'$ and boundary terms to the difference equations. The integral in 1e variational form corresponding to $(\alpha u')'$ is

$$\int_0^L \alpha(\sum_k c_k \psi_k) \psi_i' \psi_j' \,\mathrm{d}x$$

umerical integration utilizing a value of $\sum_k c_k \psi_k$ from a previous iteration ust in general be used to compute the integral. Now our aim is to integrate mbolically, as much as we can, to obtain some insight into how the finite ement method approximates this term.

To be able to derive symbolic expressions, we either turn to the group finite lement method or numerical integration in the node points. Finite element asis functions φ_i are used, we set $\alpha(u) \approx \sum_k \alpha(u_k)\varphi_k$, and then we write Further calculations are now easiest to carry out in the reference cell. V elements we can compute $L_{i,j,k}$ for the two k values that are relevant reference cell. Turning to local indices, one gets

$$L_{r,s,t}^{(e)} = \frac{1}{2h} \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}, \quad t = 0, 1,$$

where r, s, t = 0, 1 are indices over local degrees of freedom in the refere (i = q(e, r), j = q(e, s), and k = q(e, t)). The sum $\sum_k L_{i,j,k}\alpha(u_k)$ at level becomes $\sum_{t=0}^{1} L_{r,s,t}^{(e)}\alpha(\tilde{u}_t)$, where \tilde{u}_t is $u(x_{q(e,t)})$, i.e., the value of u node number t in cell number e. The element matrix becomes

$$\frac{1}{2}(\alpha(\tilde{u}_0) + \alpha(\tilde{u}_1))\frac{1}{h}\begin{pmatrix} 1 & -1\\ -1 & 1 \end{pmatrix}$$

As usual, we employ a left-to-right numbering of cells and nodes. Row i in the global matrix gets contributions from the first row of the matrix in cell i - 1 and the last row of the element matrix in cell i. number i - 1 the sum $\alpha(\tilde{u}_0) + \alpha(\tilde{u}_1)$ corresponds to $\alpha(u_{i-1}) + \alpha(u_i)$. T becomes $\alpha(u_i) + \alpha(u_{i+1})$ in cell number i. We can with this insight a the contributions to row number i in the global matrix:

$$\frac{1}{2h}(-(\alpha(u_{i-1}) + \alpha(u_i))), \quad \alpha(u_{i-1}) + 2\alpha(u_i) + \alpha(u_{i+1}), \quad \alpha(u_i) + \alpha(u_i)$$

Multiplying by the vector of unknowns u_i results in

$$-\frac{1}{h}(\frac{1}{2}(\alpha(u_i) + \alpha(u_{i+1}))(u_{i+1} - u_i) - \frac{1}{2}(\alpha(u_{i-1}) + \alpha(u_i))(u_i - u_{i-1}))(u_i - u_{i-1})$$

which is nothing but the standard finite difference discretization of -(a) with an arithmetic mean of $\alpha(u)$ (and a factor h because of the integret the finite element method).

Instead of using the group finite element method and exact integra can turn to the Trapezoidal rule for computing $\int_0^L \alpha(\sum_k u_k \varphi_k) \varphi'_i \varphi'_j dx$ at the cell level since that is most convenient:

$$\int_{-1}^{1} \alpha \left(\sum_{t=0}^{1} \tilde{u}_{t} \tilde{\varphi}_{t}\right) \frac{2}{h} \frac{d\tilde{\varphi}_{r}}{dX} \frac{2}{h} \frac{d\tilde{\varphi}_{s}}{dX} \frac{h}{2} dX = \frac{1}{2h} (-1)^{r} (-1)^{s} \int_{-1}^{1} \alpha \left(\sum_{t=0}^{1} u_{t} \tilde{\varphi}_{t}(X)\right) dX = \frac{1}{2h} (-1)^{r} (-1)^{s} \alpha \left(\sum_{t=0}^{1} \tilde{\varphi}_{t}(-1)\tilde{u}_{t}\right) + \alpha \left(\sum_{t=0}^{1} \tilde{\varphi}_{t}(1)\tilde{u}_{t}\right) = \frac{1}{2h} (-1)^{r} (-1)^{s} \left(\sum_{t=0}^{1} \tilde{\varphi}_{t}(-1)\tilde{u}_{t}\right) + \alpha \left(\sum_{t=0}^{1} \tilde{\varphi}_{t}(1)\tilde{u}_{t}\right) = \frac{1}{2h} (-1)^{r} (-1)^{s} \left(\sum_{t=0}^{1} \tilde{\varphi}_{t}(1)\tilde{u}_{t}\right) = \frac{1}{2h} (-1)^{s} \left(\sum_{t=0}^{1} \tilde{\varphi}_{t}(1)\tilde{u}_{t}\right$$

he element matrix in (46) is identical to the one in (44), showing that the roup finite element method and Trapezoidal integration are equivalent with standard finite discretization of a nonlinear Laplace term $(\alpha(u)u')'$ using an rithmetic mean for α : $[D_x \overline{x} D_x u]_i$.

We might comment on integration in the physical coordinate system too. The ommon Trapezoidal rule in Section 4.4 cannot be used to integrate derivatives ke φ'_i , because the formula is derived under the assumption of a continuous itegrand. One must instead use the more basic version of the Trapezoidal rule here all the trapezoids are summed up. This is straightforward, but I think it even more straightforward to apply the Trapezoidal rule on the reference cell nd assemble the contributions.

The term $\int auv \, dx$ in the variational form is linear and gives these terms in 1e algebraic equations:

$$\frac{ah}{6}(u_{i-1} + 4u_i + u_{i+1}) = ah[u - \frac{h^2}{6}D_x D_x u]_i$$

he final term in the variational form is the Neumann condition at the boundry: $Cv(0) = C\varphi_i(0)$. With a left-to-right numbering only i = 0 will give a particulation $Cv(0) = C\delta_{i0}$ (since $\varphi_i(0) \neq 0$ only for i = 0).

Summary.

For the equation

$$-(\alpha(u)u')' + au = f(u),$$

P1 finite elements results in difference equations where

- the term $-(\alpha(u)u')'$ becomes $-h[D_x\overline{\alpha(u)}^xD_xu]_i$ if the group finite element method or Trapezoidal integration is applied,
- f(u) becomes $hf(u_i)$ with Trapezoidal integration or the "mass matrix" representation $h[f(u) \frac{h}{6}D_xD_xf(u)]_i$ if computed by a group finite element method,
- au leads to the "mass matrix" form $ah[u \frac{h}{6}D_xD_xu]_i$.

As we now have explicit expressions for the nonlinear difference equations lso in the finite element method, a Picard or Newton method can be defined s shown for the finite difference method. Nevertheless, the general situation that we have not assembled finite difference-style equations by hand and the near system in the Picard or Newton method must therefore be defined directly rough the variational form, as shown next.

4.6 Picard iteration defined from the variational for

We address again the problem (35) with the corresponding variational fo Our aim is to define a Picard iteration based on this variational form with attempt to compute integrals symbolically as in the previous three sectio idea in Picard iteration is to use a previously computed u value in the n functions $\alpha(u)$ and f(u). Let u_{-} be the available approximation to u f previous iteration. The linearized variational form for Picard iteration

$$\int_0^L (\alpha(u_-)u'v' + auv) \,\mathrm{d}x = \int_0^L f(u_-)v \,\mathrm{d}x - Cv(0), \quad \forall v \in V.$$

This is a linear problem a(u, v) = L(v) with bilinear and linear forms

$$a(u,v) = \int_0^L (\alpha(u_-)u'v' + auv) \, \mathrm{d}x, \quad L(v) = \int_0^L f(u_-)v \, \mathrm{d}x - Cv(v) \, \mathrm{d}x$$

The associated linear system is computed the standard way. Technically back to solving $-(\alpha(x)u')' + au = f(x)$.

4.7 Newton's method defined from the variational f

Application of Newton's method to the nonlinear variational form (41) from the problem (35) requires identification of the nonlinear algebraic ec $F_i(c_0, \ldots, c_N) = 0, i \in \mathcal{I}_s$, and the Jacobian $J_{i,j} = \partial F_i / \partial c_j$ for $i, j \in \mathcal{I}_s$

The equations $F_i = 0$ follows from the variational form

$$\int_0^L (\alpha(u)u'v' + auv) \,\mathrm{d}x = \int_0^L f(u)v \,\mathrm{d}x - Cv(0), \quad \forall v \in V,$$

by choosing $v = \psi_i$, $i \in \mathcal{I}_s$, and setting $u = \sum_{j \in \mathcal{I}_s} c_j \psi_j$, maybe with a befunction to incorporate Dirichlet conditions.

With $v = \psi_i$ we have

$$F_{i} = \int_{0}^{L} (\alpha(u)u'\psi'_{i} + au\psi_{i} - f(u)\psi_{i}) \,\mathrm{d}x + C\psi_{i}(0) = 0, \quad i \in \mathcal{I}_{s} \,.$$

In the differentiations leading to the Jacobian we will frequently use the

$$\frac{\partial u}{\partial c_j} = \frac{\partial}{\partial c_j} \sum_k c_k \psi_k = \psi_j, \quad \frac{\partial u'}{\partial c_j} = \frac{\partial}{\partial c_j} \sum_k c_k \psi'_k = \psi'_j.$$

The derivation of the Jacobian goes as

$$J_{i,j} = \frac{\partial F_i}{\partial c_j} = \int_0^L \frac{\partial}{\partial c_j} (\alpha(u)u'\psi'_i + au\psi_i - f(u)\psi_i) \,\mathrm{d}x$$

$$= \int_0^L ((\alpha'(u)\frac{\partial u}{\partial c_j}u' + \alpha(u)\frac{\partial u'}{\partial c_j})\psi'_i + a\frac{\partial u}{\partial c_j}\psi_i - f'(u)\frac{\partial u}{\partial c_j}\psi_i) \,\mathrm{d}x$$

$$= \int_0^L ((\alpha'(u)\psi_ju' + \alpha(u)\psi'_j\psi'_i + a\psi_j\psi_i - f'(u)\psi_j\psi_i) \,\mathrm{d}x$$

$$= \int_0^L (\alpha'(u)u'\psi'_i\psi_j + \alpha(u)\psi'_i\psi'_j + (a - f(u))\psi_i\psi_j) \,\mathrm{d}x$$
(49)

When calculating the right-hand side vector F_i and the coefficient matrix i,j in the linear system to be solved in each Newton iteration, one must use a reviously computed u, denoted by u_{-} , for the u in (48) and (51). With this otation we have

$$F_{i} = \int_{0}^{L} \left(\alpha(u_{-})u'_{-}\psi'_{i} + (a - f(u_{-}))\psi_{i} \right) \,\mathrm{d}x - C\psi_{i}(0), \quad i \in \mathcal{I}_{s}, \tag{50}$$
$$J_{i,j} = \int_{0}^{L} \left(\alpha'(u_{-})u'_{-}\psi'_{i}\psi_{j} + \alpha(u_{-})\psi'_{i}\psi'_{j} + (a - f(u_{-}))\psi_{i}\psi_{j} \right) \,\mathrm{d}x, \quad i, j \in \mathcal{I}_{s}. \tag{51}$$

hese expressions can be used for any basis $\{\psi_i\}_{i\in\mathcal{I}_{\circ}}$. Choosing finite element inctions for ψ_i , one will normally want to compute the integral contribution ell by cell, working in a reference cell. To this end, we restrict the integration) one cell and transform the cell to [-1, 1]. The formulas (50) and (51) then nange to

$$\tilde{F}_{r}^{(e)} = \int_{-1}^{1} \left(\alpha(\tilde{u}_{-}) \tilde{u}_{-}' \tilde{\varphi}_{r}' + (a - f(\tilde{u}_{-})) \tilde{\varphi}_{r} \right) \det J \, \mathrm{d}X - C \tilde{\varphi}_{r}(0), \tag{52}$$
$$\tilde{J}_{r,s}^{(e)} = \int_{-1}^{1} \left(\alpha'(\tilde{u}_{-}) \tilde{u}_{-}' \tilde{\varphi}_{r}' \tilde{\varphi}_{s} + \alpha(\tilde{u}_{-}) \tilde{\varphi}_{r}' \tilde{\varphi}_{s}' + (a - f(\tilde{u}_{-})) \tilde{\varphi}_{r} \tilde{\varphi}_{s} \right) \det J \, \mathrm{d}X, \tag{53}$$

ith $r, s \in I_d$ runs over the local degrees of freedom. In the above formulas, $(X) = \sum_{r} \tilde{c}_{-r} \tilde{\varphi}_{r}(X)$ is the finite element expansion of u_{-} over the current -<u>1</u>].

Many finite element programs require the user to provide F_i and $J_{i,j}$. Some rograms, like FEniCS², are capable of automatically deriving $J_{i,i}$ if F_i is pecified.

)irichlet conditions. Incorporation of the Dirichlet values by assembling ontributions from all degrees of freedom and then modifying the linear system

Multi-dimensional PDE problems $\mathbf{5}$

Finite element discretization 5.1

The derivation of F_i and $J_{i,j}$ in the 1D model problem is easily genera multi-dimensional problems. For example, Backward Euler discretizatio PDE

$$u_t = \nabla \cdot (\alpha(u)\nabla u) + f(u),$$

gives the nonlinear time-discrete PDEs

$$u^n - \Delta t \nabla \cdot (\alpha(u^n) \nabla u^n) + f(u^n) = u^{n-1},$$

or with u^n simply as u and u^{n-1} as u_1 .

$$u - \Delta t \nabla \cdot (\alpha(u^n) \nabla u) - \Delta t f(u) = u_1.$$

The variational form, assuming homogeneous Neumann conditions for sin becomes

$$\int_{\Omega} (uv + \Delta t\alpha(u)\nabla u \cdot \nabla v - \Delta t f(u)v - u_1v) \,\mathrm{d}x.$$

The nonlinear algebraic equations follow from setting $v = \psi_i$ and us representation $u = \sum_{k} c_k \psi_k$, which we just write as

$$F_i = \int_{\Omega} (u\psi_i + \Delta t\alpha(u)\nabla u \cdot \nabla \psi_i - \Delta t f(u)\psi_i - u_1\psi_i) \,\mathrm{d}x \,.$$

Picard iteration needs a linearization where we use the most recent approx u_{-} to u in α and f:

$$F_i \approx \hat{F}_i = \int_{\Omega} (u\psi_i + \Delta t\alpha(u_-)\nabla u \cdot \nabla \psi_i - \Delta t f(u_-)\psi_i - u_1\psi_i) \,\mathrm{d}x$$

The equations $\hat{F}_i = 0$ are now linear and we can easily derive a linear system. the unknown coefficients $\{c_i\}_{i \in \mathcal{I}_s}$ by inserting $u = \sum_j c_j \psi_j$. In Newton's method we need to evaluate F_i with the known value u

²http://fenicsproject.org

$$F_i \approx \hat{F}_i = \int_{\Omega} (u_-\psi_i + \Delta t\alpha(u_-)\nabla u_- \cdot \nabla \psi_i - \Delta t f(u_-)\psi_i - u_1\psi_i) \,\mathrm{d}x \,. \tag{58}$$

he Jacobian is obtained by differentiating (56) and using $\partial u/\partial c_j = \psi_j$:

$$J_{i,j} = \frac{\partial F_i}{\partial c_j} = \int_{\Omega} (\psi_j \psi_i + \Delta t \alpha'(u) \psi_j \nabla u \cdot \nabla \psi_i + \Delta t \alpha(u) \nabla \psi_j \cdot \nabla \psi_i - \Delta t f'(u) \psi_j \psi_i) \, \mathrm{d}x \,.$$
(59)

he evaluation of $J_{i,j}$ as the coefficient matrix in the linear system in Newton's iethod applies the known approximation u_{-} for u:

$$J_{i,j} = \int_{\Omega} (\psi_j \psi_i + \Delta t \alpha'(u_-) \psi_j \nabla u_- \cdot \nabla \psi_i + \Delta t \alpha(u_-) \nabla \psi_j \cdot \nabla \psi_i - \Delta t f'(u_-) \psi_j \psi_i) \, \mathrm{d}x \,.$$
(60)

lopefully, these example also show how convenient the notation with u and $_{-}$ is: the unknown to be computed is always u and linearization by inserting nown (previously computed) values is a matter of adding an underscore. One an take great advantage of this quick notation in software [2].

Ion-homogeneous Neumann conditions. A natural physical flux condion for the PDE (54) takes the form of a non-homogeneous Neumann condition

$$-\alpha(u)\frac{\partial u}{\partial n} = g, \quad \boldsymbol{x} \in \partial\Omega_N, \tag{61}$$

here g is a prescribed function and $\partial \Omega_N$ is a part of the boundary of the domain . From integrating $\int_{\Omega} \nabla \cdot (\alpha \nabla u) \, dx$ by parts, we get a boundary term

$$\int_{\partial\Omega_N} \alpha(u) \frac{\partial u}{\partial u} v \,\mathrm{d}s \,. \tag{62}$$

serting the condition (61) into this term results in an integral over prescribed alues: $-\int_{\partial\Omega_N} gv \, ds$. The nonlinearity in the $\alpha(u)$ coefficient condition (61) nerefore does not contribute with a nonlinearity in the variational form.

Lobin conditions. Heat conduction problems often apply a kind of Newton's poling law, also known as a Robin condition, at the boundary:

$$-\alpha(u)\frac{\partial u}{\partial u} = h_T(u)(u - T_s(t)), \quad \boldsymbol{x} \in \partial\Omega_R,$$
(63)

here $h_T(u)$ is a heat transfer coefficient between the body (Ω) and its surbundings, T_s is the temperature of the surroundings, and $\partial \Omega_R$ is a part of the boundary where this Robin condition applies. The boundary integral (becomes

$$\int_{\partial\Omega_R} h_T(u)(u-T_s(T))v\,\mathrm{d}s,$$

by replacing $\alpha(u)\partial u/\partial u$ by $h_T(u-T_s)$. Often, $h_T(u)$ can be taken as c and then the boundary term is linear in u, otherwise it is nonlinear and con to the Jacobian in a Newton method. Linearization in a Picard meth typically use a known value in h_T , but keep the u in $u - T_s$ as un $h_T(u_-)(u - T_s(t))$.

5.2 Finite difference discretization

A typical diffusion equation

$$u_t = \nabla \cdot (\alpha(u)\nabla u) + f(u),$$

can be discretized by (e.g.) a Backward Euler scheme, which in 2D written

$$[D_t^- u = D_x \overline{\alpha}^x D_x u + D_y \overline{\alpha}^y D_y u + f(u)]_{i,j}^n.$$

We do not dive into details of boundary conditions now. Dirichlet and N conditions are handled as in linear diffusion problems.

Writing the scheme out, putting the unknown values on the left-ha and known values on the right-hand side, and introducing $\Delta x = \Delta y = h$ some writing, one gets

$$\begin{split} u_{i,j}^n &- \frac{\Delta t}{h^2} (\frac{1}{2} (\alpha(u_{i,j}^n) + \alpha(u_{i+1,j}^n))(u_{i+1,j}^n - u_{i,j}^n) \\ &- \frac{1}{2} (\alpha(u_{i-1,j}^n) + \alpha(u_{i,j}^n))(u_{i,j}^n - u_{i-1,j}^n) \\ &+ \frac{1}{2} (\alpha(u_{i,j}^n) + \alpha(u_{i,j+1}^n))(u_{i,j+1}^n - u_{i,j}^n) \\ &- \frac{1}{2} (\alpha(u_{i,j-1}^n) + \alpha(u_{i,j}^n))(u_{i,j}^n - u_{i-1,j-1}^n)) - \Delta t f(u_{i,j}^n) = u_i^n \end{split}$$

This defines a nonlinear algebraic system A(u)u = b(u). A Picard in applies old values u_{-} in α and f, or equivalently, old values for u in A b(u). The result is a linear system of the same type as those arisin $u_t = \nabla \cdot (\alpha(\boldsymbol{x})\nabla u) + f(\boldsymbol{x}, t)$.

Newton's method is as usual more involved. We first define the ner algebraic equations to be solved, drop the superscript n, and introduc u^{n-1} :

$$\begin{split} \mathbf{\dot{f}}_{i,j} &= u_{i,j}^n - \frac{\Delta t}{h^2} (\\ & \frac{1}{2} (\alpha(u_{i,j}^n) + \alpha(u_{i+1,j}^n))(u_{i+1,j}^n - u_{i,j}^n) - \frac{1}{2} (\alpha(u_{i-1,j}^n) + \alpha(u_{i,j}^n))(u_{i,j}^n - u_{i-1,j}^n) + \\ & \frac{1}{2} (\alpha(u_{i,j}^n) + \alpha(u_{i,j+1}^n))(u_{i,j+1}^n - u_{i,j}^n) - \frac{1}{2} (\alpha(u_{i,j-1}^n) + \alpha(u_{i,j}^n))(u_{i,j}^n - u_{i-1,j-1}^n)) \\ & \Delta t f(u_{i,j}^n) - u_{i,j}^{n-1} = 0 \,. \end{split}$$

is convenient to work with two indices i and j in 2D finite difference discretizaons, but it complicates the derivation of the Jacobian, which then gets four idices. The left-hand expression of an equation $F_{i,j} = 0$ is to be differentiated ith respect to each of the unknowns $u_{r,s}$ (short for $u_{r,s}^n$), $r \in \mathcal{I}_x$, $s \in \mathcal{I}_y$,

$$J_{i,j,r,s} = \frac{\partial F_{i,j}}{\partial u_{r,s}}$$

liven *i* and *j*, only a few *r* and *s* indices give nonzero contribution since $F_{i,j}$ ontains $u_{i\pm 1,j}$, $u_{i,j\pm 1}$, and $u_{i,j}$. Therefore, $J_{i,j,r,s}$ is very sparse and we can set p the left-hand side of the Newton system as

he specific derivatives become

$$\begin{aligned} J_{i,j,i-1,j} &= \frac{\partial F_{i,j}}{\partial u_{i-1,j}} \\ &= \frac{\Delta t}{h^2} (\alpha'(u_{i-1,j})(u_{i,j} - u_{i-1,j}) + \alpha(u_{i-1,j})(-1)) \\ J_{i,j,i+1,j} &= \frac{\partial F_{i,j}}{\partial u_{i+1,j}} \\ &= \frac{\Delta t}{h^2} (-\alpha'(u_{i+1,j})(u_{i+1,j} - u_{i,j}) - \alpha(u_{i-1,j})) \\ J_{i,j,i,j-1} &= \frac{\partial F_{i,j}}{\partial u_{i,j-1}} \\ &= \frac{\Delta t}{h^2} (\alpha'(u_{i,j-1})(u_{i,j} - u_{i,j-1}) + \alpha(u_{i,j-1})(-1)) \\ J_{i,j,i,j+1} &= \frac{\partial F_{i,j}}{\partial u_{i,j+1}} \\ &= \frac{\Delta t}{h^2} (-\alpha'(u_{i,j+1})(u_{i,j+1} - u_{i,j}) - \alpha(u_{i,j-1})) \end{aligned}$$

he $J_{i,j,i,j}$ entry has a few more terms. Inserting u_{-} for u in the J formula and nen forming $J\delta u = -F$ gives the linear system to be solved in each Newton eration.

5.3 Continuation methods

Picard iteration or Newton's method may diverge when solving PDEs wit nonlinearities. Relaxation with $\omega < 1$ may help, but in highly nonlinear p it can be necessary to introduce a *continuation parameter* Λ in the p $\Lambda = 0$ gives a version of the problem that is easy to solve, while $\Lambda = 1$ is th problem. The idea is then to increase Λ in steps, $\Lambda_0 = 0, \Lambda_1 < \cdots < \Lambda_n =$ use the solution from the problem with Λ_{i-1} as initial guess for the itera the problem corresponding to Λ_i .

The continuation method is easiest to understand through an e Suppose we intend to solve

$$-\nabla \cdot (||\nabla u||^q \nabla u) = f,$$

which is an equation modeling the flow of a non-Newtonian fluid th channel or pipe. For q = 0 we have the Poisson equation (correspond Newtonian fluid) and the problem is linear. A typical value for pseudo fluids may be $q_n = -0.8$. We can introduce the continuation parameter Λ such that $q = q_n \Lambda$. Let $\{\Lambda_\ell\}_{\ell=0}^n$ be the sequence of Λ values in [0,corresponding q values $\{q_\ell\}_{\ell=0}^n$. We can then solve a sequence of proble

$$-\nabla \cdot \left(||\nabla u||_{\ell}^{q} \nabla u^{\ell} \right) = f, \quad \ell = 0, \dots, n,$$

where the initial guess for iterating on u^{ℓ} is the previously computed s $u^{\ell-1}$. If a particular Λ_{ℓ} leads to convergence problems, one may try a increase in Λ : $\Lambda_* = \frac{1}{2}(\Lambda_{\ell-1} + \Lambda_{\ell})$, and repeat halving the step in convergence is reestablished.

6 Exercises

Problem 1: Determine if equations are nonlinear or a

Classify each term in the following equations as linear or nonlinear. Assu a and b are unknown numbers and that u and v are unknown function other symbols are known quantities.

1.
$$b^{2} = 1$$

2. $a + b = 1, a - 2b = 0$
3. $mu'' + \beta |u'|u' + cu = F(t)$
4. $u_{t} = \alpha u_{xx}$
5. $u_{tt} = c^{2} \nabla^{2} u$
6. $u_{t} = \nabla \cdot (\alpha(u) \nabla u) + f(x, y)$
7. $u_{t} + f(u)_{x} = 0$

8.
$$\boldsymbol{u}_t + \boldsymbol{u} \cdot \nabla \boldsymbol{u} = -\nabla p + r \nabla^2 \boldsymbol{u}, \, \nabla \cdot \boldsymbol{u} = 0 \, (\boldsymbol{u} \text{ is a vector field})$$

9. $\boldsymbol{u}' = f(\boldsymbol{u}, t)$

10. $\nabla^2 u = \lambda e^u$

Problem 2: Linearize a nonlinear vibration ODE

onsider a nonlinear vibration problem

mu'' + bu'|u'| + s(u) = F(t), (64)

here m > 0 is a constant, $b \ge 0$ is a constant, s(u) a possibly nonlinear function f u, and F(t) is a prescribed function. Such models arise from Newton's second w of motion in mechanical vibration problems where s(u) is a spring or restoring orce, mu'' is mass times acceleration, and bu'|u'| models water or air drag.

Approximate u'' by a centered finite difference $D_t D_t u$, and use a centered ifference $D_t u$ for u' as well. Observe then that s(u) does not contribute to taking the resulting algebraic equation at a time level nonlinear. Use a geometric tean to linearize the quadratic nonlinearity arising from the term bu'|u'|.

Exercise 3: Find the sparsity of the Jacobian

onsider a typical nonlinear Laplace term like $\nabla \cdot \alpha(u) \nabla u$ discretized by centered nite differences. Explain why the Jacobian corresponding to this term has the ame sparsity pattern as the matrix associated with the corresponding linear erm $\alpha \nabla^2 u$.

lint. Set up the unknowns that enter the difference stencil and find the parsity of the Jacobian that arise from the stencil.

Filename: nonlin_sparsity_Jacobian.pdf.

xercise 4: Newton's method for linear problems

uppose we have a linear system F(u) = Au - b = 0. Apply Newton's method b this system, and show that the method converges in one iteration. Filename: onlin_Newton_linear.pdf.

Exercise 5: Differentiate a highly nonlinear term

he operator $\nabla \cdot (\alpha(u)\nabla u)$ with $\alpha(u) = ||\nabla u||^q$ appears in several physical roblems, especially flow of Non-Newtonian fluids. In a Newton method one has σ carry out the differentiation $\partial \alpha(u)/\partial c_j$, for $u = \sum_k c_k \psi_k$. Show that

$$\frac{\partial}{\partial u_j} ||\nabla u||^q = q ||\nabla u||^{q-2} \nabla u \cdot \nabla \psi_j \,.$$

ilename: nonlin_differentiate.pdf.

Problem 6: Discretize a 1D problem with a nonlinear ficient

We consider the problem

$$((1+u^2)u')' = 1, \quad x \in (0,1), \quad u(0) = u(1) = 0.$$

a) Discretize (65) by a centered finite difference method on a uniform

b) Discretize (65) by a finite element method with P1 of equal leng the Trapezoidal method to compute all integrals. Set up the resulting system.

Filename: nonlin_1D_coeff_discretize.pdf.

Problem 7: Linearize a 1D problem with a nonlinear ficient

We have a two-point boundary value problem

$$((1+u^2)u')' = 1, \quad x \in (0,1), \quad u(0) = u(1) = 0.$$

a) Construct a Picard iteration method for (66) without discretizing i

b) Apply Newton's method to (66) without discretizing in space.

c) Discretize (66) by a centered finite difference scheme. Construct a method for the resulting system of nonlinear algebraic equations.

d) Discretize (66) by a centered finite difference scheme. Define the of nonlinear algebraic equations, calculate the Jacobian, and set up N method for solving the system.

Filename: nonlin_1D_coeff_linearize.pdf.

Problem 8: Finite differences for the 1D Bratu probl

We address the so-called Bratu problem

$$u'' + \lambda e^u = 0, \quad x \in (0,1), \quad u(0) = u(1) = 0,$$

where λ is a given parameter and u is a function of x. This is a widely use problem for studying numerical methods for nonlinear differential eq The problem (67) has an exact solution

$$u(x) = -2\ln\left(\frac{\cosh((x-\frac{1}{2})\theta/2)}{\cosh(\theta/4)}\right),\,$$

here θ solves

$$\theta = \sqrt{2\lambda} \cosh(\theta/4)$$

here are two solutions of (67) for $0 < \lambda < \lambda_c$ and no solution for $\lambda > \lambda_c$. For $= \lambda_c$ there is one unique solution. The critical value λ_c solves

$$1 = \sqrt{2\lambda_c} \frac{1}{4} \sinh(\theta(\lambda_c)/4) \,.$$

numerical value is $\lambda_c = 3.513830719$.

Discretize (67) by a centered finite difference method.

) Set up the nonlinear equations $F_i(u_0, u_1, \ldots, u_{N_x}) = 0$ from a). Calculate ne associated Jacobian.

Filename: nonlin_1D_Bratu_fd.pdf.

'roblem 9: Integrate functions of finite element expansions

/e shall investigate integrals on the form

$$\int_0^L f(\sum_k u_k \varphi_k(x)) \varphi_i(x) \,\mathrm{d}x,\tag{68}$$

here $\varphi_i(x)$ are P1 finite element basis functions and u_k are unknown coefficients, fore precisely the values of the unknown function u at nodes x_k . We introduce a ode numbering that goes from left to right and also that all cells have the same ngth h. Given i, the integral only gets contributions from $[x_{i-1}, x_{i+1}]$. On this iterval $\varphi_k(x) = 0$ for k < i - 1 and k > i + 1, so only three basis functions will ontribute:

$$\sum_{k} u_k \varphi_k(x) = u_{i-1} \varphi_{i-1}(x) + u_i \varphi_i(x) + u_{i+1} \varphi_{i+1}(x) \,.$$

he integral (68) now takes the simplified form

$$\int_{x_{i-1}}^{x_{i+1}} f(u_{i-1}\varphi_{i-1}(x) + u_i\varphi_i(x) + u_{i+1}\varphi_{i+1}(x))\varphi_i(x) \,\mathrm{d}x \,.$$

plit this integral in two integrals over cell L (left), $[x_{i-1}, x_i]$, and cell R (right), z_i, x_{i+1}]. Over cell L, u simplifies to $u_{i-1}\varphi_{i-1} + u_i\varphi_i$ (since $\varphi_{i+1} = 0$ on this ell), and over cell R, u simplifies to $u_i\varphi_i + u_{i+1}\varphi_{i+1}$. Make a sympt program nat can compute the integral and write it out as a difference equation. Give the f(u) formula on the command line. Try out $f(u) = u^2, \sin u, \exp u$.

Hint. Introduce symbols u_i , u_im1 , and u_ip1 for u_i , u_{i-1} , and v spectively, and similar symbols for x_i , x_{i-1} , and x_{i+1} . Find formulas basis functions on each of the two cells, make expressions for u on the t integrate over each cell, expand the answer and simplify. You can mak code and render it via http://latex.codecogs.com. Here are some app Python statements for the latter purpose:

from sympy import *

```
# expr_i holdes the integral as a sympy expression
latex_code = latex(expr_i, mode='plain')
# Replace u_im1 sympy symbol name by latex symbol u_{i-1}
latex_code = latex_code.replace('im1', '{i-1}')
# Replace u_ip1 sympy symbol name by latex symbol u_{i+1}
latex_code = latex_code.replace('ip1', '{i+1}')
# Escape (quote) latex_code so it can be sent as HTML text
import cgi
html_code = cgi.escape(latex_code)
# Make a file with HTML code for displaying the LaTeX formula
f = open('tmp.html', 'w')
# Include an image that can be clicked on to yield a new
# page with an interactive editor and display area where the
# formula can be further edited
text = """
<a href="http://www.codecogs.com/eqnedit.php?latex=%(html_code)s"
 target="_blank">
<img src="http://latex.codecogs.com/gif.latex?%(html_code)s"</pre>
 title="%(latex code)s"/>
</a>
 """ % vars()
f.write(text)
f.close()
```

The formula is displayed by loading tmp.html into a web browser.
Filename: fu_fem_int.py.

Problem 10: Finite elements for the 1D Bratu proble

We address the same 1D Bratu problem as described in Problem 8.

a) Discretize (10) by a finite element method using a uniform mesh elements. Use a group finite element method for the e^u term.

b) Set up the nonlinear equations $F_i(u_0, u_1, \ldots, u_{N_x}) = 0$ from a). C the associated Jacobian.

Filename: nonlin_1D_Bratu_fe.pdf.

Problem 11: Derive the Newton system from a varia form

We study the multi-dimensional heat conduction PDE

$$\varrho c(T)T_t = \nabla \cdot (k(T)\nabla T)$$

 ι a spatial domain Ω , with a nonlinear Robin boundary condition

$$-k(T)\frac{\partial T}{\partial n} = h(T)(T - T_s(t))$$

t the boundary $\partial\Omega$. The primary unknown is the temperature T, ϱ is the density f the solid material, c(T) is the heat capacity, k(T) is the heat conduction, h(T) a heat transfer coefficient, and $T_s(T)$ is a possibly time-dependent temperature f the surroundings.

) Use a Backward Euler or Crank-Nicolson time discretization and derive the ariational form for the spatial problem to be solved at each time level.

) Define a Picard iteration method from the variational form at a time level.

) Derive expressions for the matrix and the right-hand side of the equation /stem that arises from applying Newton's method to the variational form at a me level.

) Apply the Backward Euler or Crank-Nicolson scheme in time first. Derive Newton method at the PDE level. Make a variational form of the resulting DE at a time level.

Filename: nonlin_heat_Newton.pdf.

'roblem 12: Derive algebraic equations for nonlinear 1D leat conduction

onsider a 1D heat conduction PDE

$$\varrho c(T)T_t = (k(T)T_x)_x,$$

here ρ is the density of the solid material, c(T) is the heat capacity, T is the emperature, and k(T) is the heat conduction coefficient.

Use a uniform finite element mesh, P1 elements, and the group finite element iethod to derive the algebraic equations arising from the heat conduction PDE

) Discretize the PDE by a finite difference method. Use either a Backward uler or Crank-Nicolson scheme in time.

) Derive the matrix and right-hand side of a Newton method applied to the iscretized PDE.

Filename: nonlin_1D_heat_PDE.pdf.

Problem 13: Investigate a 1D problem with a continumethod

Flow of a pseudo-plastic power-law fluid between two flat plates can be \imath by

$$\frac{d}{dx}\left(\mu_0 \left|\frac{du}{dx}\right|^{n-1} \frac{du}{dx}\right) = -\beta, \quad u'(0) = 0, \ u(H) = 0$$

where $\beta > 0$ and $\mu_0 > 0$ are constants. A target value of n may be n =

a) Formulate a Picard iteration method directly for the differential e problem.

b) Perform a finite difference discretization of the problem in each iteration. Implement a solver that can compute u on a mesh. Verify t solver gives an exact solution for n = 1 on a uniform mesh regardless of size.

c) Given a sequence of decreasing n values, solve the problem for using the solution for the previous n as initial guess for the Picard it This is called a continuation method. Experiment with n = (1, 0.6, 0.6) $n = (1, 0.9, 0.8, \ldots, 0.2)$ and make a table of the number of Picard its versus n.

d) Derive a Newton method at the differential equation level and di the resulting linear equations in each Newton iteration with the finite di method.

e) Investigate if Newton's method has better convergence properti Picard iteration, both in combination with a continuation method.
