Purpose
Truncation error analysis provides a widely applicable framework for analyzing the accurac of finite difference schemes. This type of analysis can also be used for finite element and finite lume methods if the discrete equations are written in finite difference form. The result he analysis is an asymptotic estimate of the error in the scheme on the form $\mathrm{Ch}^{r}$, where a discretization paran and $C$ is a constant, typically dependent on the derivatives of the exact solution

Knowing $r$ gives understanding of the accuracy of the scheme. But maybe even more portant, a powerful verification method for computer codes is to check that the empirically observed convergence rates in experiments coincide with the theoretical value of $r$ found from truncation error analysis.

The analysis can be carried out by hand, by symbolic software, and also numerically. All ree methods will be illustrated. From examining the symbolic expressions of the truncation error we can add correction terms to the differential equations in order to increase the numerical accuracy.
In general, the term truncation error refers to the discrepancy that arises from performing a finite number of steps to approximate a process with infinitely many steps. The term is used a number of contexts, including truncation of infinite series, finite precision arithmetic, finite differences, and dirn equations. We shall

1 Overview of truncation error analysis

### 1.1 Abstract problem setting

Consider an abstract differential equation

$$
\mathcal{L}(u)=0,
$$

here $\mathcal{L}(u)$ is some formula involving the unknown $u$ and its derivatives. One example is $\mathcal{L}(u)=u^{\prime}(t)+a(t) u(t)-b(t)$, where $a$ and $b$ are contants or functions of time. We can discretize the differential equation and obtain a corresponding discrete model, here written as

$$
\mathcal{L}_{\Delta}(u)=0
$$

The solution $u$ of this equation is the numerical solution. To distinguish the numerical solution from the exact solution of the differential equation problem, we denote the latter by $u_{\mathrm{e}}$ and write he differential equation and its discrete counterpart as

$$
\begin{aligned}
\mathcal{L}\left(u_{\mathrm{e}}\right) & =0, \\
\mathcal{L}_{\Delta}(u) & =0 .
\end{aligned}
$$

nitial and/or boundary conditions can usually be left out of the truncation error analysis and are omitted in the following

The numerical solution $u$ is in a finite difference method computed at a collection of mesh points. The discrete equations represented by the abstract equation $\mathcal{L}(u)=0$ are usually algebraic equations involving $u$ at some neighboring mesh points.

### 1.2 Error measures

A key issue is how accurate the numerical solution is. The ultimate way of addressing this issue would be to compute the error $u_{\mathrm{e}}-u$ at the mesh points. This is usually extremely demanding In very simplified problem settings we may, however, manage to derive formulas for the numerical In very simplified problem settings we may, however, manage to derive formulas for the numerical
solution $u$, and therefore closed form expressions for the error $u_{\mathrm{e}}-u$. Such special cases can provide considerable insight regarding accuracy and stability, but the results are established for secial problems.

The error $u_{e}-u$ can be computed empirically in special cases where we know $u_{\mathrm{e}}$. Such cases can be constructed by the method of manufactured solutions, where we choose some exact solution $u_{\mathrm{e}}=v$ and fit a source term $f$ in the governing differential equation $\mathcal{L}\left(u_{\mathrm{e}}\right)=f$ such that $u_{\mathrm{e}}=v$ is a solution (i.e., $f=\mathcal{L}(v)$ ). Assuming an error model of the form $C h^{r}$, where $h$ is the discretization parameter, such as $\Delta t$ or $\Delta x$, one can estimate the convergence rate $r$. This is a widely applicable procedure, but the valididity of the results is, strictly speaking, tied to the hosen test problems.
Another error measure is to ask to what extent the exact solution $u_{\mathrm{e}}$ fits the discrete equations Clearly, $u_{\mathrm{e}}$ is in general not a solution of $\mathcal{L}_{\Delta}(u)=0$, but we can define the residual

$$
R=\mathcal{L}_{\Delta}\left(u_{\mathrm{e}}\right),
$$

and investigate how close $R$ is to zero. A small $R$ means intuitively that the discrete equations are close to the differential equation, and then we are tempted to think that $u^{n}$ must also be close to $u_{\mathrm{e}}\left(t_{n}\right)$.
The residual $R$ is known as the truncation error of the finite difference scheme $\mathcal{L}_{\Delta}(u)=0$. It appears that the truncation error is relatively straightforward to compute by hand or symbolic oftware without specializing the differential equation and the discrete model to a special case The resulting $R$ is found as a power series in the discretization parameters. The leading-order erms in the series provide an asymptotic measure of the accuracy of the numerical solutio ethod (as the discretization parameters tend to zero). An advantage of truncation error analysis mathematical expression for the numerical solution, is that the truncation error analysis revea he accuracy of the various building blocks in the numerical method and how each building block - acts the orall acuracy The analysis can therefore be used to detect building blocks with t building blocks wit Knowing the the others.
Komirially establishing conror or other error measures is important for verification of programs empirically establishing convergence rates. The forthcoming text will provide many example on how to compute truncation errors for finite difference discretizations of ODEs and PDEs.

## 2 Truncation errors in finite difference formulas

The accuracy of a finite difference formula is a fundamental issue when discretizing differential equations. We shall first go through a particular example in detail and thereafter list the truncation error in the most common finite difference approximation formulas

### 2.1 Example: The backward difference for $u^{\prime}(t)$

Consider a backward finite difference approximation of the first-order derivative $u^{\prime}$ :

$$
\begin{equation*}
\left[D_{t}^{-} u\right]^{n}=\frac{u^{n}-u^{n-1}}{\Delta t} \approx u^{\prime}\left(t_{n}\right) \tag{1}
\end{equation*}
$$

Here, $u^{n}$ means the value of some function $u(t)$ at a point $t_{n}$, and $\left[D_{t}^{-} u\right]^{n}$ is the discrete derivativ of $u(t)$ at $t=t_{n}$. The discrete derivative computed by a finite difference is not exactly equal to the derivative $u^{\prime}\left(t_{n}\right)$. The error in the approximation is

$$
\begin{equation*}
R^{n}=\left[D_{t}^{-} u\right]^{n}-u^{\prime}\left(t_{n}\right) . \tag{2}
\end{equation*}
$$

The common way of calculating $R^{n}$ is to

1. expand $u(t)$ in a Taylor series around the point where the derivative is evaluated, here $t_{n}$,
2. insert this Taylor series in (2), and
3. collect terms that cancel and simplify the expression.

The result is an expression for $R^{n}$ in terms of a power series in $\Delta t$. The error $R^{n}$ is commonly referred to as the truncation error of the finite difference formula.

The Taylor series formula often found in calculus books takes the form

$$
f(x+h)=\sum_{i=0}^{\infty} \frac{1}{i!} \frac{d^{i} f}{d x^{i}}(x) h^{i} .
$$

In our application, we expand the Taylor series around the point where the finite difference formula approximates the derivative. The Taylor series of $u^{n}$ at $t_{n}$ is simply $u\left(t_{n}\right)$, while the Taylor sereis of $u^{n-1}$ at $t_{n}$ must employ the general formula,

$$
\begin{aligned}
u\left(t_{n-1}\right)=u(t-\Delta t) & =\sum_{i=0}^{\infty} \frac{1}{i!} \frac{d^{i} u}{d t^{i}}\left(t_{n}\right)(-\Delta t)^{i} \\
& =u\left(t_{n}\right)-u^{\prime}\left(t_{n}\right) \Delta t+\frac{1}{2} u^{\prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right),
\end{aligned}
$$

where $\mathcal{O}\left(\Delta t^{3}\right)$ means a power-series in $\Delta t$ where the lowest power is $\Delta t^{3}$. We assume that $\Delta t$ i small such that $\Delta t^{p} \gg \Delta t^{q}$ if $p$ is smaller than $q$. The details of higher-order terms in $\Delta t$ are therefore not of much interest. Inserting the Taylor series above in the left-hand side of1 (2) gives rise to some algebra:

$$
\begin{aligned}
{\left[D_{t}^{-} u\right]^{n}-u^{\prime}\left(t_{n}\right) } & =\frac{u\left(t_{n}\right)-u\left(t_{n-1}\right)}{\Delta t}-u^{\prime}\left(t_{n}\right) \\
& =\frac{u\left(t_{n}\right)-\left(u\left(t_{n}\right)-u^{\prime}\left(t_{n}\right) \Delta t+\frac{1}{2} u^{\prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right)\right)}{\Delta t}-u^{\prime}\left(t_{n}\right) \\
& \left.=-\frac{1}{2} u^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)\right),
\end{aligned}
$$

which is, according to (2), the truncation error:

$$
\begin{equation*}
\left.R^{n}=-\frac{1}{2} u^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)\right) \tag{3}
\end{equation*}
$$

The dominating term for small $\Delta t$ is $-\frac{1}{2} u^{\prime \prime}\left(t_{n}\right) \Delta t$, which is proportional to $\Delta t$, and we say that the truncation error is of first order in $\Delta t$

### 2.2 Example: The forward difference for $u^{\prime}(t)$

We can analyze the approximation error in the forward difference

$$
u^{\prime}\left(t_{n}\right) \approx\left[D_{t}^{+} u\right]^{n}=\frac{u^{n+1}-u^{n}}{\Delta t}
$$

by writing

$$
R^{n}=\left[D_{t}^{+} u\right]^{n}-u^{\prime}\left(t_{n}\right),
$$

and expanding $u^{n+1}$ in a Taylor series around $t_{n}$,

$$
u\left(t_{n+1}\right)=u\left(t_{n}\right)+u^{\prime}\left(t_{n}\right) \Delta t+\frac{1}{2} u^{\prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right)
$$

The result becomes

$$
R=\frac{1}{2} u^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)
$$

showing that also the forward difference is of first order.

### 2.3 Example: The central difference for $u^{\prime}(t)$

For the central difference approximation,

$$
u^{\prime}\left(t_{n}\right) \approx\left[D_{t} u\right]^{n}, \quad\left[D_{t} u\right]^{n}=\frac{u^{n+\frac{1}{2}}-u^{n-\frac{1}{2}}}{\Delta t}
$$

we write

$$
R^{n}=\left[D_{t} u\right]^{n}-u^{\prime}\left(t_{n}\right),
$$

and expand $u\left(t_{n+\frac{1}{2}}\right)$ and $u\left(t_{n-1 / 2}\right)$ in Taylor series around the point $t_{n}$ where the derivative is evaluated. We have

$$
\begin{aligned}
u\left(t_{n+\frac{1}{2}}\right)= & u\left(t_{n}\right)+u^{\prime}\left(t_{n}\right) \frac{1}{2} \Delta t+\frac{1}{2} u^{\prime \prime}\left(t_{n}\right)\left(\frac{1}{2} \Delta t\right)^{2}+ \\
& \frac{1}{6} u^{\prime \prime \prime}\left(t_{n}\right)\left(\frac{1}{2} \Delta t\right)^{3}+\frac{1}{24} u^{\prime \prime \prime \prime \prime}\left(t_{n}\right)\left(\frac{1}{2} \Delta t\right)^{4}+ \\
& \frac{1}{120} u^{\prime \prime \prime \prime}\left(t_{n}\right)\left(\frac{1}{2} \Delta t\right)^{5}+\mathcal{O}\left(\Delta t^{6}\right), \\
u\left(t_{n-1 / 2}\right)= & u\left(t_{n}\right)-u^{\prime}\left(t_{n}\right) \frac{1}{2} \Delta t+\frac{1}{2} u^{\prime \prime}\left(t_{n}\right)\left(\frac{1}{2} \Delta t\right)^{2}- \\
& \frac{1}{6} u^{\prime \prime \prime}\left(t_{n}\right)\left(\frac{1}{2} \Delta t\right)^{3}+\frac{1}{24} u^{\prime \prime \prime \prime}\left(t_{n}\right)\left(\frac{1}{2} \Delta t\right)^{4}- \\
& \frac{1}{120} u^{\prime \prime \prime \prime \prime}\left(t_{n}\right)\left(\frac{1}{2} \Delta t\right)^{5}+\mathcal{O}\left(\Delta t^{6}\right) .
\end{aligned}
$$

Now,

$$
u\left(t_{n+\frac{1}{2}}\right)-u\left(t_{n-1 / 2}\right)=u^{\prime}\left(t_{n}\right) \Delta t+\frac{1}{24} u^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{3}+\frac{1}{960} u^{\prime \prime \prime \prime \prime}\left(t_{n}\right) \Delta t^{5}+\mathcal{O}\left(\Delta t^{7}\right)
$$

By collecting terms in $\left[D_{t} u\right]^{n}-u\left(t_{n}\right)$ we find the truncation error to be

$$
\begin{equation*}
R^{n}=\frac{1}{24} u^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) \tag{4}
\end{equation*}
$$

with only even powers of $\Delta t$. Since $R \sim \Delta t^{2}$ we say the centered difference is of second order in with
$\Delta t$.

### 2.4 Overview of leading-order error terms in finite difference formulas

Here we list the leading-order terms of the truncation errors associated with several common finite difference formulas for the first and second derivatives.

$$
\begin{align*}
{\left[D_{t} u\right]^{n} } & =\frac{u^{n+\frac{1}{2}}-u^{n-\frac{1}{2}}}{\Delta t}=u^{\prime}\left(t_{n}\right)+R^{n},  \tag{5}\\
R^{n} & =\frac{1}{24} u^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)  \tag{6}\\
{\left[D_{2 t} u\right]^{n} } & =\frac{u^{n+1}-u^{n-1}}{2 \Delta t}=u^{\prime}\left(t_{n}\right)+R^{n},  \tag{7}\\
R^{n} & =\frac{1}{6} u^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)  \tag{8}\\
{\left[D_{t}^{-} u\right]^{n} } & =\frac{u^{n}-u^{n-1}}{\Delta t}=u^{\prime}\left(t_{n}\right)+R^{n},  \tag{9}\\
R^{n} & =-\frac{1}{2} u^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)  \tag{10}\\
{\left[D_{t}^{+} u\right]^{n} } & =\frac{u^{n+1}-u^{n}}{\Delta t}=u^{\prime}\left(t_{n}\right)+R^{n},  \tag{11}\\
R^{n} & =\frac{1}{2} u^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)  \tag{12}\\
{\left[\bar{D}_{t} u\right]^{n+\theta} } & =\frac{u^{n+1}-u^{n}}{\Delta t}=u^{\prime}\left(t_{n+\theta}\right)+R^{n+\theta},  \tag{13}\\
R^{n+\theta} & =\frac{1}{2}(1-2 \theta) u^{\prime \prime}\left(t_{n+\theta}\right) \Delta t-\frac{1}{6}\left((1-\theta)^{3}-\theta^{3}\right) u^{\prime \prime \prime}\left(t_{n+\theta}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right)  \tag{14}\\
{\left[D_{t}^{2-} u\right]^{n} } & =\frac{3 u^{n}-4 u^{n-1}+u^{n-2}}{2 \Delta t}=u^{\prime}\left(t_{n}\right)+R^{n},  \tag{15}\\
R^{n} & =-\frac{1}{3} u^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right)  \tag{16}\\
{\left[D_{t} D_{t} u\right]^{n} } & =\frac{u^{n+1}-2 u^{n}+u^{n-1}}{\Delta t^{2}}=u^{\prime \prime}\left(t_{n}\right)+R^{n},  \tag{17}\\
R^{n} & =\frac{1}{12} u^{\prime \prime \prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) \tag{18}
\end{align*}
$$

It will also be convenient to have the truncation errors for various means or averages. The weighted arithmetic mean leads to

$$
\begin{align*}
{\left[\bar{u}^{t, \theta}\right]^{n+\theta} } & =\theta u^{n+1}+(1-\theta) u^{n}=u\left(t_{n+\theta}\right)+R^{n+\theta},  \tag{19}\\
R^{n+\theta} & =\frac{1}{2} u^{\prime \prime}\left(t_{n+\theta}\right) \Delta t^{2} \theta(1-\theta)+\mathcal{O}\left(\Delta t^{3}\right) . \tag{20}
\end{align*}
$$

The standard arithmetic mean follows from this formula when $\theta=1 / 2$. Expressed at point $t_{n}$ we get

$$
\begin{align*}
{\left[\bar{u}^{t}\right]^{n} } & =\frac{1}{2}\left(u^{n-\frac{1}{2}}+u^{n+\frac{1}{2}}\right)=u\left(t_{n}\right)+R^{n},  \tag{21}\\
R^{n} & =\frac{1}{8} u^{\prime \prime}\left(t_{n}\right) \Delta t^{2}+\frac{1}{384} u^{\prime \prime \prime \prime}\left(t_{n}\right) \Delta t^{4}+\mathcal{O}\left(\Delta t^{6}\right) . \tag{22}
\end{align*}
$$

The geometric mean also has an error $\mathcal{O}\left(\Delta t^{2}\right)$ :

$$
\begin{align*}
{\left[\overline{2^{t}, g}\right]^{n} } & =u^{n-\frac{1}{2}} u^{n+\frac{1}{2}}=\left(u^{n}\right)^{2}+R^{n},  \tag{23}\\
R^{n} & =-\frac{1}{4} u^{\prime}\left(t_{n}\right)^{2} \Delta t^{2}+\frac{1}{4} u\left(t_{n}\right) u^{\prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) . \tag{24}
\end{align*}
$$

The harmonic mean is also second-order accurate:

$$
\begin{align*}
{\left[\bar{u}^{t, h}\right]^{n} } & =u^{n}=\frac{2}{\frac{1}{u^{n-\frac{1}{2}}}+\frac{1}{u^{n+\frac{1}{2}}}}+R^{n+\frac{1}{2}},  \tag{25}\\
R^{n} & =-\frac{u^{\prime}\left(t_{n}\right)^{2}}{4 u\left(t_{n}\right)} \Delta t^{2}+\frac{1}{8} u^{\prime \prime}\left(t_{n}\right) \Delta t^{2} . \tag{2}
\end{align*}
$$

### 2.5 Software for computing truncation errors

We can use sympy to aid calculations with Taylor series. The derivatives can be defined as symbols, say D3f for the 3rd derivative of some function $f$. A truncated Taylor series can then be written as $f+D 1 f * h+D 2 f * h * * 2 / 2$. The following class takes some symbol $f$ for the function in question and makes a list of symbols for the derivatives. The __call__ method computes the symbolic form of the series truncated at num terms terms.

## import sympy as sp

class TaylorSeries:
Class for symbolic Taylor series.""
self.f $=f$
self. $\mathrm{N}=$ num_term
\# Introduce symbols for the derivatives
for i in range (1, self. $N+1$ ):
def _-
terms $=$ self $f$ truncated Taylor series at $\mathrm{x}+\mathrm{h} . \mathrm{"}$ "
terms =self.f
for in in range $(1$, self. $N+1)$ :
terms $+=$ sp.Rational(1, sp.factorial(i))*self.df $[i] * h * * i$
return terms
We may, for example, use this class to compute the truncation error of the Forward Eule finite difference formula:
>>> from truncation_errors import TaylorSeries
>>> from sympy import
$\ggg \mathrm{u}, \mathrm{dt}=$ symbols ('u d
>>> u_Taylor = TaylorSeries(u, 4)
>> un Taylor $^{\text {Tdt }}$ )

$\xrightarrow[\ggg \text { FE }]{ }=\left(u_{-}\right.$Taylor (dt) -u$) / \mathrm{dt}$
(D1u*dt + D2u*dt**2/2 + D3u*dt**3/6 + D4u*dt
>>
Diu + D $2 u * d t / 2+$

+ D3u*dt**2/6 + D4u*dt**3/24

The truncation error consists of the terms after the first one ( $u^{\prime}$ )
The module file trunc/truncation_errors.py ${ }^{1}$ contains another class Diffop with symbolic expressions for most of the truncation errors listed in the previous section. For example:

```
\>> from truncation-errors import Diff0p
>>> from sympy import
>>> diffop = DiffOp(u, independent_variable='t'
>>> diffop ['geometric_mean']
M,
D1u + D2u*dt/2 + D3u*dt**2/6 + D4u*dt**3/2
l
```

The indexing of diffop applies names that correspond to the operators: $\operatorname{Dtp}$ for $D_{t}^{+}$, $\operatorname{Dtm}$ for $D_{t}^{-}$ Dt for $D_{t}, \mathrm{D} 2 \mathrm{t}$ for $D_{2 t}$, DtDt for $D_{t} D_{t}$.

## 3 Truncation errors in exponential decay ODE

We shall now compute the truncation error of a finite difference scheme for a differential equation Our first problem involves the following the linear ODE modeling exponential decay,

$$
\begin{equation*}
u^{\prime}(t)=-a u(t) . \tag{27}
\end{equation*}
$$

### 3.1 Truncation error of the Forward Euler scheme

We begin with the Forward Euler scheme for discretizing (27):

$$
\begin{equation*}
\left[D_{t}^{+} u=-a u\right]^{n} . \tag{28}
\end{equation*}
$$

The idea behind the truncation error computation is to insert the exact solution $u_{e}$ of the differential equation problem (27) in the discrete equations (28) and find the residual that arises because $u_{\mathrm{e}}$ does not solve the discrete equations. Instead, $u_{\mathrm{e}}$ solves the discrete equations with a esidual $R^{n}$.

$$
\begin{equation*}
\left[D_{t}^{+} u_{\mathrm{e}}+a u_{\mathrm{e}}=R\right]^{n} . \tag{29}
\end{equation*}
$$

From (11)-(12) it follows that

$$
\left[D_{t}^{+} u_{\mathrm{e}}\right]^{n}=u_{\mathrm{e}}^{\prime}\left(t_{n}\right)+\frac{1}{2} u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right),
$$

which inserted in (29) results in

$$
u_{\mathrm{e}}^{\prime}\left(t_{n}\right)+\frac{1}{2} u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)+a u_{\mathrm{e}}\left(t_{n}\right)=R^{n}
$$

Now, $u_{\mathrm{e}}^{\prime}\left(t_{n}\right)+a u_{\mathrm{e}}^{n}=0$ since $u_{\mathrm{e}}$ solves the differential equation. The remaining terms constitute the residual:

$$
\begin{equation*}
R^{n}=\frac{1}{2} u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right) . \tag{30}
\end{equation*}
$$

This is the truncation error $R^{n}$ of the Forward Euler scheme.
${ }^{1}$ http://tinyurl.com/jvzzcfn/trunc/truncation_errors.py

Because $R^{n}$ is proportional to $\Delta t$, we say that the Forward Euler scheme is of first order in $\Delta t$. However, the truncation error is just one error measure, and it is not equal to the true erro $u_{\mathrm{e}}^{n}-u^{n}$. For this simple model problem we can compute a range of different error measures fo he Forward Euler scheme, including the true error $u_{\mathrm{e}}^{n}-u^{n}$, and all of them have dominatin terms proportional to $\Delta t$

### 3.2 Truncation error of the Crank-Nicolson scheme

For the Crank-Nicolson scheme,

$$
\begin{equation*}
\left[D_{t} u=-a u\right]^{n+\frac{1}{2}}, \tag{31}
\end{equation*}
$$

we compute the truncation error by inserting the exact solution of the ODE and adding a residual we
$R$,

$$
\begin{equation*}
\left[D_{t} u_{\mathrm{e}}+a{\overline{u_{\mathrm{e}}}}^{t}=R\right]^{n+\frac{1}{2}} . \tag{32}
\end{equation*}
$$

The term $\left[D_{t} u_{\mathrm{e}}\right]^{n+\frac{1}{2}}$ is easily computed from (5)-(6) by replacing $n$ with $n+\frac{1}{2}$ in the formula,

$$
\left[D_{t} u_{\mathrm{e}}\right]^{n+\frac{1}{2}}=u^{\prime}\left(t_{n+\frac{1}{2}}\right)+\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n+\frac{1}{2}}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) .
$$

The arithmetic mean is related to $u\left(t_{n+\frac{1}{2}}\right)$ by (21)-(22) so

$$
\left[a \bar{u}_{\mathrm{e}}^{t}\right]^{n+\frac{1}{2}}=u\left(t_{n+\frac{1}{2}}\right)+\frac{1}{8} u^{\prime \prime}\left(t_{n}\right) \Delta t^{2}++\mathcal{O}\left(\Delta t^{4}\right)
$$

Inserting these expressions in (32) and observing that $u_{\mathrm{e}}^{\prime}\left(t_{n+\frac{1}{2}}\right)+a u_{\mathrm{e}}^{n+\frac{1}{2}}=0$, because $u_{\mathrm{e}}(t)$ solves the $\operatorname{ODE} u^{\prime}(t)=-a u(t)$ at any point $t$, we find that

$$
\begin{equation*}
R^{n+\frac{1}{2}}=\left(\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n+\frac{1}{2}}\right)+\frac{1}{8} u^{\prime \prime}\left(t_{n}\right)\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) \tag{33}
\end{equation*}
$$

Here, the truncation error is of second order because the leading term in $R$ is proportional to $\Delta t^{2}$. At this point it is wise to redo some of the computations above to establish the truncation error of the Backward Euler scheme, see Exercise 4.

### 3.3 Truncation error of the $\theta$-rule

We may also compute the truncation error of the $\theta$-rule,

$$
\left[\bar{D}_{t} u=-a \bar{u}^{t, \theta}\right]^{n+\theta}
$$

Our computational task is to find $R^{n+\theta}$ in

$$
\left[\bar{D}_{t} u_{\mathrm{e}}+a \bar{u}_{\mathrm{e}}^{t, \theta}=R\right]^{n+\theta} .
$$

From (13)-(14) and (19)-(20) we get expressions for the terms with $u_{\mathrm{e}}$. Using that $u_{\mathrm{e}}^{\prime}\left(t_{n+\theta}\right)+$ $a u_{\mathrm{e}}\left(t_{n+\theta}\right)=0$, we end up with

$$
\begin{align*}
R^{n+\theta}= & \left(\frac{1}{2}-\theta\right) u_{\mathrm{e}}^{\prime \prime}\left(t_{n+\theta}\right) \Delta t+\frac{1}{2} \theta(1-\theta) u_{\mathrm{e}}^{\prime \prime}\left(t_{n+\theta}\right) \Delta t^{2}+  \tag{34}\\
& \frac{1}{2}\left(\theta^{2}-\theta+3\right) u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n+\theta}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right)
\end{align*}
$$

For $\theta=1 / 2$ the first-order term vanishes and the scheme is of second order, while for $\theta \neq 1 / 2$ we only have a first-order scheme.

### 3.4 Using symbolic software

he previously mentioned truncation_error module can be used to automate the Taylor serie expansions and the process of collecting terms. Here is an example on possible use:

```
fom truncation_error
```

def decay():
a, a = symbols('u a')
diffop $=$ Diff0p( $u$, independent_variable $='$ ' ,

Diu $+\mathrm{a} * \mathrm{u}$

BE = diffop ['DD' $]+$ a*u
theta $=$ diffop ['barDt'] + a*diffop['weighted_arithmetic_mean']
theta $=$ sm.simplify (sm.expand(theta))

$\mathrm{R}=\begin{gathered}\text { \{'FE': } \mathrm{FE}-\mathrm{ODE}, \mathrm{SE}, \\ \text { 'theta': theta-ODE }\}\end{gathered}$
return R
The returned dictionary becomes

```
decay: {
```

```
    lol
```

\}

The results are in correspondence with our hand-derived expressions.

### 3.5 Empirical verification of the truncation error

The task of this section is to demonstrate how we can compute the truncation error $R$ numerically or example, the truncation error of the Forward Euler scheme applied to the decay ODE $u^{\prime}=-u a$ is

$$
\begin{equation*}
R^{n}=\left[D_{t}^{+} u_{\mathrm{e}}+a u_{\mathrm{e}}\right]^{n} . \tag{35}
\end{equation*}
$$

If we happen to know the exact solution $u_{\mathrm{e}}(t)$, we can easily evaluate $R^{n}$ from the above formula To estimate how $R$ varies with the discretization parameter $\Delta t$, which has been our focus in the previous mathematical derivations, we first make the assumption that $R=C \Delta t^{r}$ fo appropriate constants $C$ and $r$ and small enough $\Delta t$. The rate $r$ can be estimated from a series of experiments where $\Delta t$ is varied. Suppose we have $m$ experiments $\left(\Delta t_{i}, R_{i}\right), i=0, \ldots, m-1$. Fo wo consecutive experiments $\left(\Delta t_{i-1}, R_{i-1}\right)$ and $\left(\Delta t_{i}, R_{i}\right)$, a corresponding $r_{i-1}$ can be estimated by

$$
r_{i-1}=\frac{\ln \left(R_{i-1} / R_{i}\right)}{\ln \left(\Delta t_{i-1} / \Delta t_{i}\right)},
$$

for $i=1, \ldots, m-1$. Note that the truncation error $R_{i}$ varies through the mesh, so (36) is to be applied pointwise. A complicating issue is that $R_{i}$ and $R_{i-1}$ refer to different meshes Pointwise comparisons of the truncation error at a certain point in all meshes therefore requires any computed $R$ to be restricted to the coarsest mesh and that all finer meshes contain all the points in the coarsest mesh. Suppose we have $N_{0}$ intervals in the coarsest mesh. Inserting superscript $n$ in (36), where $n$ counts mesh points in the coarsest mesh, $n=0, \ldots, N_{0}$, leads to he formula

$$
\begin{equation*}
r_{i-1}^{n}=\frac{\ln \left(R_{i-1}^{n} / R_{i}^{n}\right)}{\ln \left(\Delta t_{i-1} / \Delta t_{i}\right)} \tag{37}
\end{equation*}
$$

Experiments are most conveniently defined by $N_{0}$ and a number of refinements $m$. Suppose each mesh have twice as many cells $N_{i}$ as the previous one:

$$
N_{i}=2^{i} N_{0}, \quad \Delta t_{i}=T N_{i}^{-1},
$$

where $[0, T]$ is the total time interval for the computations. Suppose the computed $R_{i}$ values on the mesh with $N_{i}$ intervals are stored in an array R[i] (R being a list of arrays, one for each nesh). Restricting this $R_{i}$ function to the coarsest mesh means extracting every $N_{i} / N_{0}$ point and is done as follows
stride $=\mathbb{N}[i] / N \_0$
$R[i]=R[i][::$ stride $]$
The quantity $\mathrm{R}[\mathrm{i}][\mathrm{n}]$ now corresponds to $R_{i}^{n}$.
In addition to estimating $r$ for the pointwise values of $R=C \Delta t^{r}$, we may also consider an integrated quantity on mesh $i$

$$
\begin{equation*}
R_{I, i}=\left(\Delta t_{i} \sum_{n=0}^{N_{i}}\left(R_{i}^{n}\right)^{2}\right)^{\frac{1}{2}} \approx \int_{0}^{T} R_{i}(t) d t \tag{38}
\end{equation*}
$$

The sequence $R_{I, i}, i=0, \ldots, m-1$, is also expected to behave as $C \Delta t^{r}$, with the same $r$ as for the pointwise quantity $R$, as $\Delta t \rightarrow 0$.
The function below computes the $R_{i}$ and $R_{I, i}$ quantities, plots them and compares with the theoretically derived truncation error ( $\mathrm{R}_{-} \mathrm{a}$ ) if available.

## import numpy as np import scitools.std as plt

\# Convergence rates
r_R_I $=$ convergence_rates (dt, R_I)

$\mathrm{R}=\mathrm{np} . \operatorname{array}(\mathrm{R}) \quad$ \# two-dim. numpy array
$\mathrm{r}_{-} \mathrm{R}=[$ convergence_rates $(\mathrm{dt}, \mathrm{R}[: \mathrm{n}])$ [-1]
for $n$ in range(len(t,coarse) $)$ ]

The first makeplot block demonstrates how to build up two figures in parallel, using plt.figure (i) to create and switch to figure number i. Figure numbers start at 1. A logarithmic scale is used on the $y$ axis since we expect that $R$ as a function of time (or mesh points) is
exponential. The reason is that the theoretical estimate (30) contains $u_{\mathrm{e}}^{\prime \prime}$, which for the present model goes like $e^{-a t}$. Taking the logarithm makes a straight line

The code follows closely the previously stated mathematical formulas, but the statements for computing the convergence rates might deserve an explanation. The generic help functio convergence_rate(h, E) computes and returns $r_{i-1}, i=1, \ldots, m-1$ from (37), given $\Delta t_{i}$ in h and $R_{i}^{n}$ in E :
def convergence_rates (h, E):
$\underset{r=}{\text { from math import }} \operatorname{liog}) / \log (E[i] / E[i-1]) / \log (h[i] / h[i-1])$
$=\underset{f o r}{\log (E[i]}$ in $\operatorname{range}(1, \operatorname{li-1}(\mathrm{len}(\mathrm{h}))]$
return
Calling r_R_I = convergence_rates(dt, R_I) computes the sequence of rates $r_{0}, r_{1}, \ldots, r_{m-2}$ for the model $R_{I} \sim \Delta t^{r}$, while the statements

compute the final rate $r_{m-2}$ for $R^{n} \sim \Delta t^{r}$ at each mesh point $t_{n}$ in the coarsest mesh. This latter computation deserves more explanation. Since $\mathrm{R}[\mathrm{i}][\mathrm{n}]$ holds the estimated truncation rror $R_{i}^{n}$ on mesh $i$, at point $t_{n}$ in the coarsest mesh, $\mathrm{R}[:, \mathrm{n}]$ picks out the sequence $R_{i}^{n}$ for $=0, \ldots, m-1$. The convergence_rate function computes the rates at $t_{n}$, and by indexing [-1] on the returned array from convergence_rate, we pick the rate $r_{m-2}$, which we believe is the best estimation since it is based on the two finest meshes.

The estimate function is available in a module trunc_empir. $\mathrm{py}^{2}$. Let us apply this function to estimate the truncation error of the Forward Euler scheme. We need a function decay_FE(dt, N) that can compute (35) at the points in a mesh with time step dt and $N$ intervals:
import numpy as np
import trunc_empir
def decay_FE(dt,N):
$t=$ np. linspace ( $0, N * d t, N+1$
i_e $=\mathrm{I} * \mathrm{np}$. $\exp (-\mathrm{a} * \mathrm{t}) \quad \#$ exact solution, $I$ and a are global
$\mathrm{R}=\mathrm{u}_{\mathrm{n}} \mathrm{e}$.zeros( N$)$

\# Theoretical expression for the trunction error
Ra $=0.5 * \mathrm{I} *(-\mathrm{a}) * * 2 * \mathrm{np}$. $\exp (-\mathrm{a} * \mathrm{t}) * \mathrm{dt}$
return R, t[:-1], R_a[:-1]
if - name $_{--}=$, - main ${ }^{\prime}$ ':
runc_a $=2$ global variables needed in decay_FE

The estimated rates for the integrated truncation error $R_{I}$ become 1.1, 1.0, and 1.0 for this sequence of four meshes. All the rates for $R^{n}$, computed as $r_{-} R$, are also very close to 1 at al mesh points. The agreement between the theoretical formula (30) and the computed quantity ${ }^{2}$ http://tinyurl.com/jvzzcfn/trunc/trunc_empir.py
(ref(35)) is very good, as illustrated in Figures 1 and 2. The program trunc_decay_FE.py ${ }^{3}$ wa sed to perform the simulations and it can easily be modified to test other schemes (see als Exericse 5).

Figure 1: Estimated truncation error at mesh points for different meshes

### 3.6 Increasing the accuracy by adding correction terms

Now we ask the question: can we add terms in the differential equation that can help increase the order of the truncation error? To be precise, let us revisit the Forward Euler scheme fo ${ }^{\prime}=-a u$, insert the exact solution $u_{\mathrm{e}}$, include a residual $R$, but also include new terms $C$

$$
\begin{equation*}
\left[D_{t}^{+} u_{\mathrm{e}}+a u_{\mathrm{e}}=C+R\right]^{n} \tag{39}
\end{equation*}
$$

Inserting the Taylor expansions for $\left[D_{t}^{+} u_{\mathrm{e}}\right]^{n}$ and keeping terms up to 3rd order in $\Delta t$ gives the equation

$$
\frac{1}{2} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right) \Delta t-\frac{1}{6} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime \prime}\left(t_{n}\right) \Delta t^{3}+\mathcal{O}\left(\Delta t^{4}\right)=C^{n}+R^{n} .
$$

Can we find $C^{n}$ such that $R^{n}$ is $\mathcal{O}\left(\Delta t^{2}\right)$ ? Yes, by setting

$$
C^{n}=\frac{1}{2} u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right) \Delta t,
$$

${ }^{3} \mathrm{http}: / /$ tinyur1.com/jvzzcfn/trunc/trunc_decay_FE.py

Figure 2: Difference between theoretical and estimated truncation error at mesh points for different meshes
we manage to cancel the first-order term and

$$
R^{n}=\frac{1}{6} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right)
$$

The correction term $C^{n}$ introduces $\frac{1}{2} \Delta t u^{\prime \prime}$ in the discrete equation, and we have to get rid of the derivative $u^{\prime \prime}$. One idea is to approximate $u^{\prime \prime}$ by a second-order accurate finite difference ormula, $u^{\prime \prime} \approx\left(u^{n+1}-2 u^{n}+u^{n-1}\right) / \Delta t^{2}$, but this introduces an additional time level with $u^{n-1}$ Another approach is to rewrite $u^{\prime \prime}$ in terms of $u^{\prime}$ or $u$ using the ODE:

$$
u^{\prime}=-a u \quad \Rightarrow \quad u^{\prime \prime}=-a u^{\prime}=-a(-a u)=a^{2} u .
$$

This means that we can simply set $C^{n}=\frac{1}{2} a^{2} \Delta t u^{n}$. We can then either solve the discrete equation

$$
\begin{equation*}
\left[D_{t}^{+} u=-a u+\frac{1}{2} a^{2} \Delta t u\right]^{n}, \tag{40}
\end{equation*}
$$

or we can equivalently discretize the perturbed ODE

$$
\begin{equation*}
u^{\prime}=-\hat{a} u, \quad \hat{a}=a\left(1-\frac{1}{2} a \Delta t\right), \tag{41}
\end{equation*}
$$

by a Forward Euler method. That is, we replace the original coefficient $a$ by the perturbed oefficient $\hat{a}$. Observe that $\hat{a} \rightarrow a$ as $\Delta t \rightarrow 0$.

The Forward Euler method applied to (41) results in

$$
\left[D_{t}^{+} u=-a\left(1-\frac{1}{2} a \Delta t\right) u\right]^{n} .
$$

We can control our computations and verify that the truncation error of the scheme above is indeed $\mathcal{O}\left(\Delta t^{2}\right)$.

Another way of revealing the fact that the perturbed ODE leads to a more accurate solution is to look at the amplification factor. Our scheme can be written as

$$
u^{n+1}=A u^{n}, \quad A=1-\hat{a} \Delta t=1-p+\frac{1}{2} p^{2}, \quad p=a \Delta t,
$$

The amplification factor $A$ as a function of $p=a \Delta t$ is seen to be the first three terms of the Taylor series for the exact amplification factor $e^{-p}$. The Forward Euler scheme for $u=-a u$ give only the first two terms $1-p$ of the Taylor series for $e^{-p}$. That is, using $\hat{a}$ increases the order of the accuracy in the amplification factor.
Instead of replacing $u^{\prime \prime}$ by $a^{2} u$, we use the relation $u^{\prime \prime}=-a u^{\prime}$ and add a term $-\frac{1}{2} a \Delta t u^{\prime}$ in he ODE:

$$
u^{\prime}=-a u-\frac{1}{2} a \Delta t u^{\prime} \quad \Rightarrow \quad\left(1+\frac{1}{2} a \Delta t\right) u^{\prime}=-a u .
$$

Using a Forward Euler method results in

$$
\left(1+\frac{1}{2} a \Delta t\right) \frac{u^{n+1}-u^{n}}{\Delta t}=-a u^{n},
$$

hich after some algebra can be written as

$$
u^{n+1}=\frac{1-\frac{1}{2} a \Delta t}{1+\frac{1}{2} a \Delta t} u^{n} .
$$

This is the same formula as the one arising from a Crank-Nicolson scheme applied to $u^{\prime}=-a u$ It now recommended to do Exercise 6 and repeat the above steps to see what kind of correction term is needed in the Backward Euler scheme to make it second order
The Crank-Nicolson scheme is a bit more challenging to analyze, but the ideas and techniques are the same. The discrete equation reads

$$
\left[D_{t} u=-a u\right]^{n+\frac{1}{2}},
$$

and the truncation error is defined through

$$
\left[D_{t} u_{\mathrm{e}}+a{\overline{u_{\mathrm{e}}}}^{t}=C+R\right]^{n+\frac{1}{2}},
$$

where we have added a correction term. We need to Taylor expand both the discrete derivative and the arithmetic mean with aid of $(5)-(6)$ and (21)-(22), respectively. The result is

$$
\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n+\frac{1}{2}}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)+\frac{a}{8} u_{\mathrm{e}}^{\prime \prime}\left(t_{n+\frac{1}{2}}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)=C^{n+\frac{1}{2}}+R^{n+\frac{1}{2}} .
$$

The goal now is to make $C^{n+\frac{1}{2}}$ cancel the $\Delta t^{2}$ terms:

$$
C^{n+\frac{1}{2}}=\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n+\frac{1}{2}}\right) \Delta t^{2}+\frac{a}{8} u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right) \Delta t^{2} .
$$

Using $u^{\prime}=-a u$, we have that $u^{\prime \prime}=a^{2} u$, and we find that $u^{\prime \prime \prime}=-a^{3} u$. We can therefore solve the perturbed ODE problem

$$
u^{\prime}=-\hat{a} u, \quad \hat{a}=a\left(1-\frac{1}{12} a^{2} \Delta t^{2}\right),
$$

by the Crank-Nicolson scheme and obtain a method that is of fourth order in $\Delta t$. Exercise 7 encourages you to implement these correction terms and calculate empirical convergence rates to verify that higher-order accuracy is indeed obtained in real computations.

### 3.7 Extension to variable coefficients

Let us address the decay ODE with variable coefficients,

$$
u^{\prime}(t)=-a(t) u(t)+b(t)
$$

discretized by the Forward Euler scheme,

$$
\left[D_{t}^{+} u=-a u+b\right]^{n} .
$$

The truncation error $R$ is as always found by inserting the exact solution $u_{\mathrm{e}}(t)$ in the discrete scheme:

$$
\begin{equation*}
\left[D_{t}^{+} u_{\mathrm{e}}+a u_{\mathrm{e}}-b=R\right]^{n} . \tag{43}
\end{equation*}
$$

Using (11)-(12),

$$
u_{\mathrm{e}}^{\prime}\left(t_{n}\right)-\frac{1}{2} u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)+a\left(t_{n}\right) u_{\mathrm{e}}\left(t_{n}\right)-b\left(t_{n}\right)=R^{n}
$$

Because of the ODE,

$$
u_{\mathrm{e}}^{\prime}\left(t_{n}\right)+a\left(t_{n}\right) u_{\mathrm{e}}\left(t_{n}\right)-b\left(t_{n}\right)=0,
$$

so we are left with the result

$$
\begin{equation*}
R^{n}=-\frac{1}{2} u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right) \tag{44}
\end{equation*}
$$

We see that the variable coefficients do not pose any additional difficulties in this case. Exercise 8 takes the analysis above one step further to the Crank-Nicolson scheme.

### 3.8 Exact solutions of the finite difference equations

Having a mathematical expression for the numerical solution is very valuable in program verification since we then know the exact numbers that the program should produce. Looking at fication since we then know the exact numbers that the program should produce. Looking at that all but two of the $R$ expressions contains a second or higher order derivative of $u_{\mathrm{e}}$. The that all but two of the $R$ expressions contains a second or higher order derivative of $u_{\mathrm{e}}$. The even $u_{\mathrm{e}}$ in case of the harmonic mean. So, apart from these two means, choosing $u_{\mathrm{e}}$ to be a linear function of $t, u_{\mathrm{e}}=c t+d$ for constants $c$ and $d$ will make the truncation error vanish since $u^{\prime \prime}=0$. Consqeuently, the truncation error of a finite difference scheme will be zero since the $u_{\mathrm{e}}^{\prime \prime}=0$. Consqeuently, the truncation error of a finite difference scheme will be zero since the various approximations used wins. In a particular differtial
In a particular differential equation problem, the reasoning above can be used to determine if we expect a linear $u_{e}$ to fulfill the discrete equations. To actually prove that this is true, we can either compute the truncation error and see that it vanishes, or we can simply insert $u_{\mathrm{e}}(t)=c t+d$
in the scheme and see that it fulfills the equations. The latter method is usually the simplest. It will often be necessary to add some source term to the ODE in order to allow a linear solution. Many ODEs are discretized by centered differences. From Section 2.4 we see that all the centered difference formulas have truncation errors involving $u_{\mathrm{e}}^{\prime \prime \prime}$ or higher-order derivatives. A quadratic solution, e.g., $u_{\mathrm{e}}(t)=t^{2}+c t+d$, will then make the truncation errors vanish. This observation can be used to test if a quadratic solution will fulfil the discrete equations. Note that quadratic solution will not obey the equations for a Crank-Nicolson scheme for $u=-a u+b$

### 3.9 Computing truncation errors in nonlinear problems

The general nonlinear ODE

$$
\begin{equation*}
u^{\prime}=f(u, t) \tag{45}
\end{equation*}
$$

can be solved by a Crank-Nicolson scheme

$$
\begin{equation*}
\left[D_{t} u^{\prime}=\bar{f}^{t}\right]^{n+\frac{1}{2}} . \tag{46}
\end{equation*}
$$

The truncation error is as always defined as the residual arising when inserting the exact solution $u_{\mathrm{e}}$ in the scheme:

$$
\begin{equation*}
\left[D_{t} u_{\mathrm{e}}^{\prime}-\bar{f}^{t}=R\right]^{n+\frac{1}{2}} . \tag{47}
\end{equation*}
$$

Using (21)-(22) for $\bar{f}^{t}$ results in

$$
\begin{aligned}
{\left[\bar{f}^{t}\right]^{n+\frac{1}{2}} } & =\frac{1}{2}\left(f\left(u_{\mathrm{e}}^{n}, t_{n}\right)+f\left(u_{\mathrm{e}}^{n+1}, t_{n+1}\right)\right) \\
& =f\left(u_{\mathrm{e}}^{n+\frac{1}{2}}, t_{n+\frac{1}{2}}\right)+\frac{1}{8} u_{\mathrm{e}}^{\prime \prime}\left(t_{n+\frac{1}{2}}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)
\end{aligned}
$$

With (5)-(6) the discrete equations (47) lead to

$$
u_{\mathrm{e}}^{\prime}\left(t_{n+\frac{1}{2}}\right)+\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n+\frac{1}{2}}\right) \Delta t^{2}-f\left(u_{\mathrm{e}}^{n+\frac{1}{2}}, t_{n+\frac{1}{2}}\right)-\frac{1}{8} u^{\prime \prime}\left(t_{n+\frac{1}{2}}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)=R^{n+\frac{1}{2}} .
$$

Since $u_{\mathrm{e}}^{\prime}\left(t_{n+\frac{1}{2}}\right)-f\left(u_{\mathrm{e}}^{n+\frac{1}{2}}, t_{n+\frac{1}{2}}\right)=0$, the truncation error becomes

$$
R^{n+\frac{1}{2}}=\left(\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n+\frac{1}{2}}\right)-\frac{1}{8} u^{\prime \prime}\left(t_{n+\frac{1}{2}}\right)\right) \Delta t^{2}
$$

The computational techniques worked well even for this nonlinear ODE.
4 Truncation errors in vibration ODEs

### 4.1 Linear model without damping

The next example on computing the truncation error involves the following ODE for vibration problems:

$$
\begin{equation*}
u^{\prime \prime}(t)+\omega^{2} u(t)=0 . \tag{48}
\end{equation*}
$$

Here, $\omega$ is a given constant.

The truncation error of a centered finite difference scheme. Using a standard, secondordered, central difference for the second-order derivative time, we have the scheme

$$
\begin{equation*}
\left[D_{t} D_{t} u+\omega^{2} u=0\right]^{n} . \tag{49}
\end{equation*}
$$

Inserting the exact solution $u_{\mathrm{e}}$ in this equation and adding a residual $R$ so that $u_{\mathrm{e}}$ can fulfil he equation results in

$$
\begin{equation*}
\left[D_{t} D_{t} u_{\mathrm{e}}+\omega^{2} u_{\mathrm{e}}=R\right]^{n} . \tag{50}
\end{equation*}
$$

To calculate the truncation error $R^{n}$, we use (17)-(18), i.e.,

$$
\left[D_{t} D_{t} u_{\mathrm{e}}\right]^{n}=u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right)+\frac{1}{12} u_{\mathrm{e}}^{\prime \prime \prime \prime}\left(t_{n}\right) \Delta t^{2},
$$

and the fact that $u_{\mathrm{e}}^{\prime \prime}(t)+\omega^{2} u_{\mathrm{e}}(t)=0$. The result is

$$
\begin{equation*}
R^{n}=\frac{1}{12} u_{\mathrm{e}}^{\prime \prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) \tag{51}
\end{equation*}
$$

The truncation error of approximating $u^{\prime}(0)$. The initial conditions for (48) are $u(0)=I$ and $u^{\prime}(0)=V$. The latter involves a finite difference approximation. The standard choice

$$
\left[D_{2 t} u=V\right]^{0}
$$

where $u^{-1}$ is eliminated with the aid of the discretized ODE for $n=0$, involves a centered difference with an $\mathcal{O}\left(\Delta t^{2}\right)$ truncation error given by (7)-(8). The simpler choice

$$
\left[D_{t}^{+} u=V\right]^{0},
$$

is based on a forward difference with a truncation error $\mathcal{O}(\Delta t)$. A central question is if this initial error will impact the order of the scheme throughout the simulation. Exercise 11 asks you to quickly perform an experiment to investigate this question

Truncation error of the equation for the first step. We have shown that the truncation error of the difference used to approximate the initial condition $u^{\prime}(0)=0$ is $\mathcal{O}\left(\Delta t^{2}\right)$, but can also investigate the difference equation used for the first step. In a truncation error setting, the right way to view this equation is not to use the initial condition $\left[D_{2 t} u=V\right]^{0}$ to express $u^{-1}=u^{1}-2 \Delta t V$ in order to eliminate $u^{-1}$ from the discretized differential equation, but the ther way around: the fundamental equation is the discretized initial condition $\left[D_{2 t} u=V\right]^{0}$ and we use the discretized ODE $\left[D_{t} D_{t}+\omega^{2} u=0\right]^{0}$ to eliminate $u^{-1}$ in the disretized initial condition. From $\left[D_{t} D_{t}+\omega^{2} u=0\right]^{0}$ we have

$$
u^{-1}=2 u^{0}-u^{1}-\Delta t^{2} \omega^{2} u^{0},
$$

which inserted in $\left[D_{2 t} u=V\right]^{0}$ gives

$$
\begin{equation*}
\frac{u^{1}-u^{0}}{\Delta t}+\frac{1}{2} \omega^{2} \Delta t u^{0}=V . \tag{52}
\end{equation*}
$$

The first term can be recognized as a forward difference such that the equation can be written in operator notation as

$$
\left[D_{t}^{+} u+\frac{1}{2} \omega^{2} \Delta t u=V\right]^{0} .
$$

The truncation error is defined as

$$
\left[D_{t}^{+} u_{\mathrm{e}}+\frac{1}{2} \omega^{2} \Delta t u_{\mathrm{e}}-V=R\right]^{0} .
$$

Using (11)-(12) with one more term in the Taylor series, we get that

$$
u_{\mathrm{e}}^{\prime}(0)+\frac{1}{2} u_{\mathrm{e}}^{\prime \prime}(0) \Delta t+\frac{1}{6} u_{\mathrm{e}}^{\prime \prime \prime}(0) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right)+\frac{1}{2} \omega^{2} \Delta t u_{\mathrm{e}}(0)-V=R^{n} .
$$

Now, $u_{\mathrm{e}}^{\prime}(0)=V$ and $u_{\mathrm{e}}^{\prime \prime}(0)=-\omega^{2} u_{\mathrm{e}}(0)$ so we get

$$
R^{n}=\frac{1}{6} u_{\mathrm{e}}^{\prime \prime \prime}(0) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right)
$$

There is another way of analyzing the discrete initial condition, because eliminating $u^{-1}$ via the discretized ODE can be expressed as

$$
\begin{equation*}
\left[D_{2 t} u+\Delta t\left(D_{t} D_{t} u-\omega^{2} u\right)=V\right]^{0} \tag{53}
\end{equation*}
$$

Writing out (53) shows that the equation is equivalent to (52). The truncation error is defined by

$$
\left[D_{2 t} u_{\mathrm{e}}+\Delta t\left(D_{t} D_{t} u_{\mathrm{e}}-\omega^{2} u_{\mathrm{e}}\right)=V+R\right]^{0} .
$$

Replacing the difference via (7)-(8) and (17)-(18), as well as using $u_{\mathrm{e}}^{\prime}(0)=V$ and $u_{\mathrm{e}}^{\prime \prime}(0)=$ $-\omega^{2} u_{\mathrm{e}}(0)$, gives

$$
R^{n}=\frac{1}{6} u^{\prime \prime \prime}(0) \Delta t^{2}+\mathcal{O}\left(\Delta t^{3}\right) .
$$

Computing correction terms. The idea of using correction terms to increase the order of $R^{n}$ can be applied as described in Section 3.6. We look at

$$
\left[D_{t} D_{t} u_{\mathrm{e}}+\omega^{2} u_{\mathrm{e}}=C+R\right]^{n},
$$

and observe that $C^{n}$ must be chosen to cancel the $\Delta t^{2}$ term in $R^{n}$. That is,

$$
C^{n}=\frac{1}{12} u_{\mathrm{e}}^{\prime \prime \prime \prime}\left(t_{n}\right) \Delta t^{2} .
$$

oret rid of the 4th-order derivative we can use the differential equation: $u^{\prime \prime}=-\omega^{u}$, which implies $u^{\prime \prime \prime \prime}=\omega^{4} u$. Adding the correction term to the ODE results in

$$
u^{\prime \prime}+\omega^{2}\left(1-\frac{1}{12} \omega^{2} \Delta t^{2}\right) u=0
$$

Solving this equation by the standard scheme

$$
\left[D_{t} D_{t} u+\omega^{2}\left(1-\frac{1}{12} \omega^{2} \Delta t^{2}\right) u=0\right]^{n}
$$

will result in a scheme with trunction error $\mathcal{O}\left(\Delta t^{4}\right)$.
We can use another set of arguments to justify that (54) leads to a higher-order method. Mathematical analysis of the scheme (49) reveals that the numerical frequency $\tilde{\omega}$ is (approximately as $\Delta t \rightarrow 0$ )

$$
\tilde{\omega}=\omega\left(1+\frac{1}{24} \omega^{2} \Delta t^{2}\right) .
$$

22

One can therefore attempt to replace $\omega$ in the ODE by a slightly smaller $\omega$ since the numerics will make it larger:

$$
\left[u^{\prime \prime}+\left(\omega\left(1-\frac{1}{24} \omega^{2} \Delta t^{2}\right)\right)^{2} u=0\right.
$$

Expanding the squared term and omitting the higher-order term $\Delta t^{4}$ gives exactly the ODE (54). Experiments show that $u^{n}$ is computed to 4 th order in $\Delta t$.

### 4.2 Model with damping and nonlinearity

The model (48) can be extended to include damping $\beta u^{\prime}$, a nonlinear restoring (spring) force $s(u)$, and some known excitation force $F(t)$

$$
\begin{equation*}
m u^{\prime \prime}+\beta u^{\prime}+s(u)=F(t) . \tag{55}
\end{equation*}
$$

The coefficient $m$ usually represents the mass of the system. This governing equation can by discretized by centered differences:

$$
\begin{equation*}
\left[m D_{t} D_{t} u+\beta D_{2 t} u+s(u)=F\right]^{n} . \tag{56}
\end{equation*}
$$

The exact solution $u_{\mathrm{e}}$ fulfills the discrete equations with a residual term

$$
\begin{equation*}
\left[m D_{t} D_{t} u_{\mathrm{e}}+\beta D_{2 t} u_{\mathrm{e}}+s\left(u_{\mathrm{e}}\right)=F+R\right]^{n} . \tag{57}
\end{equation*}
$$

Using (17)-(18) and (7)-(8) we ge

$$
\begin{aligned}
{\left[m D_{t} D_{t} u_{\mathrm{e}}+\beta D_{2 t} u_{\mathrm{e}}\right]^{n}=} & m u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right)+\beta u_{\mathrm{e}}^{\prime}\left(t_{n}\right)+ \\
& \left(\frac{m}{12} u_{\mathrm{e}}^{\prime \prime \prime \prime}\left(t_{n}\right)+\frac{\beta}{6} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right)\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)
\end{aligned}
$$

Combining this with the previous equation, we can collect the terms

$$
m u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right)+\beta u_{\mathrm{e}}^{\prime}\left(t_{n}\right)+\omega^{2} u_{\mathrm{e}}\left(t_{n}\right)+s\left(u_{\mathrm{e}}\left(t_{n}\right)\right)-F^{n},
$$

and set this sum to zero because $u_{\mathrm{e}}$ solves the differential equation. We are left with the truncation error

$$
\begin{equation*}
R^{n}=\left(\frac{m}{12} u_{\mathrm{e}}^{\prime \prime \prime \prime}\left(t_{n}\right)+\frac{\beta}{6} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right)\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right), \tag{58}
\end{equation*}
$$

so the scheme is of second order.
According to (58), we can add correction terms

$$
C^{n}=\left(\frac{m}{12} u_{\mathrm{e}}^{\prime \prime \prime \prime}\left(t_{n}\right)+\frac{\beta}{6} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right)\right) \Delta t^{2},
$$

to the right-hand side of the ODE to obtain a fourth-order scheme. However, expressing $u^{\prime \prime \prime \prime}$ and $u^{\prime \prime \prime}$ in terms of lower-order derivatives is now harder because the differential equation is more complicated:

$$
\begin{aligned}
u^{\prime \prime \prime} & =\frac{1}{m}\left(F^{\prime}-\beta u^{\prime \prime}-s^{\prime}(u) u^{\prime}\right), \\
u^{\prime \prime \prime \prime} & =\frac{1}{m}\left(F^{\prime \prime}-\beta u^{\prime \prime \prime}-s^{\prime \prime}(u)\left(u^{\prime}\right)^{2}-s^{\prime}(u) u^{\prime \prime}\right), \\
& =\frac{1}{m}\left(F^{\prime \prime}-\beta \frac{1}{m}\left(F^{\prime}-\beta u^{\prime \prime}-s^{\prime}(u) u^{\prime}\right)-s^{\prime \prime}(u)\left(u^{\prime}\right)^{2}-s^{\prime}(u) u^{\prime \prime}\right) .
\end{aligned}
$$

It is not impossible to discretize the resulting modified ODE, but it is up to debate whether correction terms are feasible and the way to go. Computing with a smaller $\Delta t$ is usually alway possible in these problems to achieve the desired accuracy

### 4.3 Extension to quadratic damping

Instead of the linear damping term $\beta u^{\prime}$ in (55) we now consider quadratic damping $\beta\left|u^{\prime}\right| u^{\prime}$ :

$$
m u^{\prime \prime}+\beta\left|u^{\prime}\right| u^{\prime}+s(u)=F(t) .
$$

A centered difference for $u^{\prime}$ gives rise to a nonlinearity, which can be linearized using a geometric mean: $\left\lceil\left.\left|u^{\prime}\right| u^{\prime}\right|^{n} \approx \left\lvert\,\left[\left.u^{\prime}\right|^{n-\frac{1}{2}} \left\lvert\,\left[u^{\prime} \|^{n+\frac{1}{2}}\right.\right.\right.$. The resulting scheme becomes \right.\right.

$$
\begin{equation*}
\left[m D_{t} D_{t} u\right]^{n}+\beta\left|\left[D_{t} u\right]^{n-\frac{1}{2}}\right|\left[D_{t} u\right]^{n+\frac{1}{2}}+s\left(u^{n}\right)=F^{n} . \tag{60}
\end{equation*}
$$

The truncation error is defined through

$$
\begin{equation*}
\left[m D_{t} D_{t} u_{\mathrm{e}}\right]^{n}+\beta\left|\left[D_{t} u_{\mathrm{e}}\right]^{n-\frac{1}{2}}\right|\left[D_{t} u_{\mathrm{e}}\right]^{n+\frac{1}{2}}+s\left(u_{\mathrm{e}}^{n}\right)-F^{n}=R^{n} . \tag{61}
\end{equation*}
$$

We start with expressing the truncation error of the geometric mean. According to (23)-(24),

$$
\left|\left[D_{t} u_{\mathrm{e}}\right]^{n-\frac{1}{2}}\right|\left[D_{t} u_{\mathrm{e}}\right]^{n+\frac{1}{2}}=\left[\left|D_{t} u_{\mathrm{e}}\right| D_{t} u_{\mathrm{e}}\right]^{n}-\frac{1}{4} u^{\prime}\left(t_{n}\right)^{2} \Delta t^{2}+\frac{1}{4} u\left(t_{n}\right) u^{\prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) .
$$

Using (5)-(6) for the $D_{t} u_{\mathrm{e}}$ factors results in

$$
\left[\left|D_{t} u_{\mathrm{e}}\right| D_{t} u_{\mathrm{e}}\right]^{n}=\left|u_{\mathrm{e}}^{\prime}+\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)\right|\left(u_{\mathrm{e}}^{\prime}+\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)\right)
$$

We can remove the absolute value since it essentially gives a factor 1 or -1 only. Calculating the product, we have the leading-order terms

$$
\left[D_{t} u_{\mathrm{e}} D_{t} u_{\mathrm{e}}\right]^{n}=\left(u_{\mathrm{e}}^{\prime}\left(t_{n}\right)\right)^{2}+\frac{1}{12} u_{\mathrm{e}}\left(t_{n}\right) u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)
$$

With

$$
m\left[D_{t} D_{t} u_{\mathrm{e}}\right]^{n}=m u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right)+\frac{m}{12} 2_{\mathrm{e}}^{\prime \prime \prime \prime}\left(t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right),
$$

and using the differential equation on the form $m u^{\prime \prime}+\beta\left(u^{\prime}\right)^{2}+s(u)=F$, we end up with

$$
R^{n}=\left(\frac{m}{12} u_{\mathrm{e}}^{\prime \prime \prime \prime}\left(t_{n}\right)+\frac{\beta}{12} u_{\mathrm{e}}\left(t_{n}\right) u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n}\right)\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) .
$$

This result demonstrates that we have second-order accuracy also with quadratic damping. The ey elements that lead to the second-order accuracy is that the difference approximations $\mathcal{O}\left(\Delta t^{2}\right)$ and the geometric mean approximation is also of $\mathcal{O}\left(\Delta t^{2}\right)$.

### 4.4 The general model formulated as first-order ODEs

The second-order model (59) can be formulated as a first-order system,

$$
\begin{align*}
u^{\prime} & =v  \tag{62}\\
v^{\prime} & =\frac{1}{m}(F(t)-\beta|v| v-s(u)) . \tag{63}
\end{align*}
$$

The system (62)-(62) can be solved either by a forward-backward scheme or a centered scheme on a staggered mesh.

The forward-backward scheme. The discretization is based on the idea of stepping (62) forward in time and then using a backward difference in (63) with the recently computed (and therefore known) $u$ :

$$
\begin{align*}
& {\left[D_{t}^{+} u=v\right]^{n}} \\
& {\left[D_{t}^{-} v=\frac{1}{m}(F(t)-\beta|v| v-s(u))\right]^{n+1} .} \tag{65}
\end{align*}
$$

The term $|v| v$ gives rise to a nonlinearity $\left|v^{n+1}\right| v^{n+1}$, which can be linearized as $\left|v^{n}\right| v^{n+1}$ :

$$
\begin{align*}
{\left[D_{t}^{+} u\right.} & =v]^{n},  \tag{66}\\
{\left[D_{t}^{-} v\right]^{n+1} } & =\frac{1}{m}\left(F\left(t_{n+1}\right)-\beta\left|v^{n}\right| v^{n+1}-s\left(u^{n+1}\right)\right) . \tag{67}
\end{align*}
$$

Each ODE will have a truncation error when inserting the exact solutions $u_{\mathrm{e}}$ and $v_{\mathrm{e}}$ in
E4) (64)-(65)

$$
\begin{align*}
{\left[D_{t}^{+} u_{\mathrm{e}}\right.} & \left.=v_{\mathrm{e}}+R_{u}\right]^{n}, \\
{\left[D_{t}^{-} v_{\mathrm{e}}\right]^{n+1} } & =\frac{1}{m}\left(F\left(t_{n+1}\right)-\beta\left|v_{\mathrm{e}}\left(t_{n}\right)\right| v_{\mathrm{e}}\left(t_{n+1}\right)-s\left(u_{\mathrm{e}}\left(t_{n+1}\right)\right)\right)+R_{v}^{n+1} . \tag{69}
\end{align*}
$$

Application of (11)-(12) and (9)-(10) in (68) and (69), respectively, gives

$$
\begin{align*}
u_{\mathrm{e}}^{\prime}\left(t_{n}\right)+\frac{1}{2} u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)= & v_{\mathrm{e}}\left(t_{n}\right)+R_{u}^{n},  \tag{70}\\
v_{\mathrm{e}}^{\prime}\left(t_{n+1}\right)-\frac{1}{2} v_{\mathrm{e}}^{\prime \prime}\left(t_{n+1}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)= & \frac{1}{m}\left(F\left(t_{n+1}\right)-\beta\left|v_{\mathrm{e}}\left(t_{n}\right)\right| v_{\mathrm{e}}\left(t_{n+1}\right)+\right. \\
& s\left(u_{\mathrm{e}}\left(t_{n+1}\right)\right)+R_{v}^{n}
\end{align*}
$$

Since $u_{\mathrm{e}}^{\prime}=v_{\mathrm{e}},(70)$ gives

$$
R_{u}^{n}=\frac{1}{2} u_{\mathrm{e}}^{\prime \prime}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right) .
$$

In (71) we can collect the terms that constitute the ODE, but the damping term has the wrong form. Let us drop the absolute value in the damping term for simplicity. Adding a substracting the right form $v^{n+1} v^{n+1}$ helps:

$$
\begin{gathered}
v_{\mathrm{e}}^{\prime}\left(t_{n+1}\right)-\frac{1}{m}\left(F\left(t_{n+1}\right)-\beta v_{\mathrm{e}}\left(t_{n+1}\right) v_{\mathrm{e}}\left(t_{n+1}\right)+s\left(u_{\mathrm{e}}\left(t_{n+1}\right)\right)+\right. \\
\left.\left(\beta v_{\mathrm{e}}\left(t_{n}\right) v_{\mathrm{e}}\left(t_{n+1}\right)-\beta v_{\mathrm{e}}\left(t_{n+1}\right) v_{\mathrm{e}}\left(t_{n+1}\right)\right)\right),
\end{gathered}
$$

which reduces to

$$
\begin{aligned}
\frac{\beta}{m} v_{\mathrm{e}}\left(t_{n+1}\left(v_{\mathrm{e}}\left(t_{n}\right)-v_{\mathrm{e}}\left(t_{n+1}\right)\right)\right. & =\frac{\beta}{m} v_{\mathrm{e}}\left(t_{n+1}\left[D_{t}^{-} v_{\mathrm{e}}\right]^{n+1} \Delta t\right. \\
& =\frac{\beta}{m} v_{\mathrm{e}}\left(t_{n+1}\left(v_{\mathrm{e}}^{\prime}\left(t_{n+1}\right) \Delta t+-\frac{1}{2} v_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n+1}\right) \Delta t^{+} \mathcal{O}\left(\Delta t^{3}\right)\right) .\right.
\end{aligned}
$$

We end with $R_{u}^{n}$ and $R_{v}^{n+1}$ as $\mathcal{O}(\Delta t)$, simply because all the building blocks in the schemes the forward and backward differences and the linearization trick) are only first-order accurate However, this analysis is misleading: the building blocks play together in a way that makes he scheme second-order accurate. This is shown by considering an alternative, yet equivalent ormulation of the above scheme.

A centered scheme on a staggered mesh. We now introduce a staggered mesh where $w$ akes it mesh points $t_{n}$ and $v$ at points $t_{n+\frac{1}{2}}$ in between the $u$ poi

$$
\begin{align*}
& {\left[D_{t} u=v\right]^{n-\frac{1}{2}},}  \tag{72}\\
& {\left[D_{t} v=\frac{1}{m}(F(t)-\beta|v| v-s(u))\right]^{n} .} \tag{73}
\end{align*}
$$

The term $\left|v^{n}\right| v^{n}$ causes trouble since $v^{n}$ is not computed, only $v^{n-\frac{1}{2}}$ and $v^{n+\frac{1}{2}}$. Using geometric mean, we can express $\left|v^{n}\right| v^{n}$ in terms of known quantities: $\left|v^{n}\right| v^{n} \approx\left|v^{n-\frac{1}{2}}\right| v^{n+\frac{1}{2}}$. We then have

$$
\begin{align*}
{\left[D_{t} u\right]^{n-\frac{1}{2}} } & =v^{n-\frac{1}{2}},  \tag{74}\\
{\left[D_{t} v\right]^{n} } & =\frac{1}{m}\left(F\left(t_{n}\right)-\beta\left|v^{n-\frac{1}{2}}\right| v^{n+\frac{1}{2}}-s\left(u^{n}\right)\right) . \tag{75}
\end{align*}
$$

The truncation error in each equation fulfills

$$
\begin{aligned}
{\left[D_{t} u_{\mathrm{e}}\right]^{n-\frac{1}{2}} } & =v_{\mathrm{e}}\left(t_{n-\frac{1}{2}}\right)+R_{u}^{n-\frac{1}{2}}, \\
{\left[D_{t} v_{\mathrm{e}}\right]^{n} } & =\frac{1}{m}\left(F\left(t_{n}\right)-\beta\left|v_{\mathrm{e}}\left(t_{n-\frac{1}{2}}\right)\right| v_{\mathrm{e}}\left(t_{n+\frac{1}{2}}\right)-s\left(u^{n}\right)\right)+R_{v}^{n} .
\end{aligned}
$$

The truncation error of the centered differences is given by (5)-(6), and the geometric mean approximation analysis can be taken from (23)-(24). These results lead to

$$
u_{\mathrm{e}}^{\prime}\left(t_{n-\frac{1}{2}}\right)+\frac{1}{24} u_{\mathrm{e}}^{\prime \prime \prime}\left(t_{n-\frac{1}{2}}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)=v_{\mathrm{e}}\left(t_{n-\frac{1}{2}}\right)+R_{u}^{n-\frac{1}{2}},
$$

and

$$
v_{\mathrm{e}}^{\prime}\left(t_{n}\right)=\frac{1}{m}\left(F\left(t_{n}\right)-\beta\left|v_{\mathrm{e}}\left(t_{n}\right)\right| v_{\mathrm{e}}\left(t_{n}\right)+\mathcal{O}\left(\Delta t^{2}\right)-s\left(u^{n}\right)\right)+R_{v}^{n} .
$$

The ODEs fulfilled by $u_{\mathrm{e}}$ and $v_{\mathrm{e}}$ are evident in these equations, and we achieve second-order accuracy for the truncation error in both equations:

$$
R_{u}^{n-\frac{1}{2}}=\mathcal{O}\left(\Delta t^{2}\right), \quad R_{v}^{n}=\mathcal{O}\left(\Delta t^{2}\right)
$$

Comparing (74)-(75) with (66)-(67), we can hopefully realize that these schemes are equivalent which becomes clear when we implement both). The obvious advantage with the staggered mesh approach is that we can all the way use second-order accurate building blocks and in this way concince ourselves that the resulting scheme has an error of $\mathcal{O}\left(\Delta t^{2}\right)$.

## 5 Truncation errors in wave equations

### 5.1 Linear wave equation in 1D

The standard, linear wave equation in 1D for a function $u(x, t)$ reads

$$
\begin{equation*}
\frac{\partial^{2} u}{\partial t^{2}}=c^{2} \frac{\partial^{2} u}{\partial x^{2}}+f(x, t), \quad x \in(0, L), t \in(0, T] \tag{76}
\end{equation*}
$$

where $c$ is the constant wave velocity of the physical medium $[0, L]$. The equation can also be more compactly written as

$$
\begin{equation*}
u_{t t}=c^{2} u_{x x}+f, \quad x \in(0, L), t \in(0, T], \tag{77}
\end{equation*}
$$

Centered, second-order finite differences are a natural choice for discretizing the derivatives, leading to

$$
\begin{equation*}
\left[D_{t} D_{t} u=c^{2} D_{x} D_{x} u+f\right]_{i}^{n} . \tag{78}
\end{equation*}
$$

Inserting the exact solution $u_{\mathrm{e}}(x, t)$ in (78) makes this function fulfill the equation if we add the term $R$ :

$$
\begin{equation*}
\left[D_{t} D_{t} u_{\mathrm{e}}=c^{2} D_{x} D_{x} u_{\mathrm{e}}+f+R\right]_{i}^{n} \tag{79}
\end{equation*}
$$

Our purpose is to calculate the truncation error $R$. From (17)-(18) we have that

$$
\left[D_{t} D_{t} u_{\mathrm{e}}\right]_{i}^{n}=u_{\mathrm{e}, t t}\left(x_{i}, t_{n}\right)+\frac{1}{12} u_{\mathrm{e}, t t t t}\left(x_{i}, t_{n}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right)
$$

when we use a notation taking into account that $u_{\mathrm{e}}$ is a function of two variables and that derivatives must be partial derivatives. The notation $u_{\mathrm{e}, t t}$ means $\partial^{2} u_{\mathrm{e}} / \partial t^{2}$

The same formula may also be applied to the $x$-derivative term:

$$
\left[D_{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n}=u_{\mathrm{e}, x x}\left(x_{i}, t_{n}\right)+\frac{1}{12} u_{\mathrm{e}, x x x x}\left(x_{i}, t_{n}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right),
$$

Equation (81) now becomes

$$
u_{\mathrm{e}, t t}+\frac{1}{12} u_{\mathrm{e}, t t t t}\left(x_{i}, t_{n}\right) \Delta t^{2}=c^{2} u_{\mathrm{e}, x x}+c^{2} \frac{1}{12} u_{\mathrm{e}, x x x x}\left(x_{i}, t_{n}\right) \Delta x^{2}+f\left(x_{i}, t_{n}\right)+
$$

$$
\mathcal{O}\left(\Delta t^{4}, \Delta x^{4}\right)+R_{i}^{n} .
$$

Because $u_{\mathrm{e}}$ fulfills the partial differential equation (PDE) (77), the first, third, and fifth terms cancel out, and we are left with

$$
\begin{equation*}
R_{i}^{n}=\frac{1}{12} u_{\mathrm{e}, t t t t}\left(x_{i}, t_{n}\right) \Delta t^{2}-c^{2} \frac{1}{12} u_{\mathrm{e}, x x x x}\left(x_{i}, t_{n}\right) \Delta x^{2}+\mathcal{O}\left(\Delta t^{4}, \Delta x^{4}\right), \tag{80}
\end{equation*}
$$

showing that the scheme (78) is of second order in the time and space mesh spacing.

### 5.2 Finding correction terms

Can we add correction terms to the PDE and increase the order of $R_{i}^{n}$ in (80)? The starting point is

$$
\begin{equation*}
\left[D_{t} D_{t} u_{\mathrm{e}}=c^{2} D_{x} D_{x} u_{\mathrm{e}}+f+C+R\right]_{i}^{n} \tag{81}
\end{equation*}
$$

From the previous analysis we simply get (80) again, but now with $C$

$$
\begin{equation*}
R_{i}^{n}+C_{i}^{n}=\frac{1}{12} u_{\mathrm{e}, t t t t}\left(x_{i}, t_{n}\right) \Delta t^{2}-c^{2} \frac{1}{12} u_{\mathrm{e}, x x x x}\left(x_{i}, t_{n}\right) \Delta x^{2}+\mathcal{O}\left(\Delta t^{4}, \Delta x^{4}\right) . \tag{82}
\end{equation*}
$$

The idea is to let $C_{i}^{n}$ cancel the $\Delta t^{2}$ and $\Delta x^{2}$ terms to make $R_{i}^{n}=\mathcal{O}\left(\Delta t^{4}, \Delta x^{4}\right)$ :

$$
C_{i}^{n}=\frac{1}{12} u_{\mathrm{e}, t t t t}\left(x_{i}, t_{n}\right) \Delta t^{2}-c^{2} \frac{1}{12} u_{\mathrm{e}, x x x x}\left(x_{i}, t_{n}\right) \Delta x^{2} .
$$

Essentially, it means that we add a new term

$$
C=\frac{1}{12}\left(u_{t t t t} \Delta t^{2}-c^{2} u_{x x x x} \Delta x^{2}\right),
$$

to the right-hand side of the PDE. We must either discretize these 4th-order derivatives directly or rewrite them in terms of lower-order derivatives with the aid of the PDE. The latter approach is more feasible. From the PDE we have that
so

$$
\frac{\partial^{2}}{\partial t^{2}}=c^{2} \frac{\partial^{2}}{\partial x^{2}}
$$

$$
u_{t t t t}=c^{2} u_{x x t t}, \quad u_{x x x x}=c^{-2} u_{t t x x}
$$

Assuming $u$ is smooth enough that $u_{x x t t}=u_{t t x x}$, these relations lead to

$$
C=\frac{1}{12}\left(\left(c^{2} \Delta t^{2}-\Delta x^{2}\right) u_{x x}\right)_{t t}
$$

A natural discretization is

$$
C_{i}^{n}=\frac{1}{12}\left(\left(c^{2} \Delta t^{2}-\Delta x^{2}\right)\left[D_{x} D_{x} D_{t} D_{t} u\right]_{i}^{n}\right.
$$

Writing out $\left[D_{x} D_{x} D_{t} D_{t} u\right]_{i}^{n}$ as $\left[D_{x} D_{x}\left(D_{t} D_{t} u\right)\right]_{i}^{n}$ gives

$$
\begin{array}{ll}
\frac{1}{\Delta t^{2}}\left(\frac{u_{i+1}^{n+1}-2 u_{i+1}^{n}+u_{i+1}^{n-1}}{\Delta x^{2}}-2\right. & \\
& \frac{u_{i}^{n+1}-2 u_{i}^{n}+u_{i}^{n-1}}{\Delta x^{2}}+
\end{array}
$$

Now the unknown values $u_{i+1}^{n+1}, u_{i}^{n+1}$, and $u_{i-1}^{n+1}$ are coupled, and we must solve a tridiagonal system to find them. This is in principle straightforward, but it results in an implicit finite difference schemes, while we had a convenient explicit scheme without the correction terms.

### 5.3 Extension to variable coefficients

Now we address the variable coefficient version of the linear 1D wave equation,

$$
\frac{\partial^{2} u}{\partial t^{2}}=\frac{\partial}{\partial x}\left(\lambda(x) \frac{\partial u}{\partial x}\right)
$$

or written more compactly as

$$
\begin{equation*}
u_{t t}=\left(\lambda u_{x}\right)_{x} \tag{83}
\end{equation*}
$$

The discrete counterpart to this equation, using arithmetic mean for $\lambda$ and centered differences, reads

$$
\begin{equation*}
\left[D_{t} D_{t} u=D_{x} \bar{\lambda}^{x} D_{x} u\right]_{i}^{n} \tag{84}
\end{equation*}
$$

The truncation error is the residual $R$ in the equation

$$
\begin{equation*}
\left[D_{t} D_{t} u_{\mathrm{e}}=D_{x} \bar{\lambda}^{x} D_{x} u_{\mathrm{e}}+R\right]_{i}^{n} . \tag{85}
\end{equation*}
$$

The difficulty in the present is how to compute the truncation error of the term $\left[D_{x} \bar{\lambda}^{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n}$. We start by writing out the outer operator:

$$
\begin{equation*}
\left[D_{x} \bar{\lambda}^{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n}=\frac{1}{\Delta x}\left(\left[\bar{\lambda}^{x} D_{x} u_{\mathrm{e}}\right]_{i+\frac{1}{2}}^{n}-\left[\bar{\lambda}^{x} D_{x} u_{\mathrm{e}}\right]_{i-\frac{1}{2}}^{n}\right) \tag{86}
\end{equation*}
$$

With the aid of (5)-(6) and (21)-(22) we have

$$
\begin{aligned}
{\left[D_{x} u_{\mathrm{e}}\right]_{i+\frac{1}{2}}^{n}=} & u_{\mathrm{e}, x}\left(x_{i+\frac{1}{2}}, t_{n}\right)+\frac{1}{24} u_{\mathrm{e}, x x x}\left(x_{i+\frac{1}{2}}, t_{n}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right), \\
{\left[\bar{\lambda}^{x}\right]_{i+\frac{1}{2}}=} & \lambda\left(x_{i+\frac{1}{2}}\right)+\frac{1}{8} \lambda^{\prime \prime}\left(x_{i+\frac{1}{2}}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right), \\
{\left[\bar{\lambda}^{x} D_{x} u_{\mathrm{e}}\right]_{i+\frac{1}{2}}^{n}=} & \left(\lambda\left(x_{i+\frac{1}{2}}\right)+\frac{1}{8} \lambda^{\prime \prime}\left(x_{i+\frac{1}{2}}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right)\right) \times \\
& \left(u_{\mathrm{e}, x}\left(x_{i+\frac{1}{2}}, t_{n}\right)+\frac{1}{24} u_{\mathrm{e}, x x x}\left(x_{i+\frac{1}{2}}, t_{n}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right)\right) \\
= & \lambda\left(x_{i+\frac{1}{2}}\right) u_{\mathrm{e}, x}\left(x_{i+\frac{1}{2}}, t_{n}\right)+\lambda\left(x_{i+\frac{1}{2}}\right) \frac{1}{24} u_{\mathrm{e}, x x x}\left(x_{i+\frac{1}{2}}, t_{n}\right) \Delta x^{2}+ \\
& u_{\mathrm{e}, x}\left(x_{i+\frac{1}{2}}\right) \frac{1}{8} \lambda^{\prime \prime}\left(x_{i+\frac{1}{2}}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right) \\
= & {\left[\lambda u_{\mathrm{e}, x}\right]_{i+\frac{1}{2}}^{n}+G_{i+\frac{1}{2}}^{n} \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right), }
\end{aligned}
$$

where we have introduced the short form

$$
G_{i+\frac{1}{2}}^{n}=\left(\frac{1}{24} u_{\mathrm{e}, x x x}\left(x_{i+\frac{1}{2}}, t_{n}\right) \lambda\left(\left(x_{i+\frac{1}{2}}\right)+u_{\mathrm{e}, x}\left(x_{i+\frac{1}{2}}, t_{n}\right) \frac{1}{8} \lambda^{\prime \prime}\left(x_{i+\frac{1}{2}}\right)\right) \Delta x^{2} .\right.
$$

Similarly, we find that

$$
\left[\lambda^{x} D_{x} u_{\mathrm{e}}\right]_{i-\frac{1}{2}}^{n}=\left[\lambda u_{\mathrm{e}, x}\right]_{i-\frac{1}{2}}^{n}+G_{i-\frac{1}{2}}^{n} \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right)
$$

Inserting these expressions in the outer operator (86) results in

$$
\begin{aligned}
{\left[D_{x} \bar{\lambda}^{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n} } & =\frac{1}{\Delta x}\left(\left[\lambda^{x} D_{x} u_{\mathrm{e}}\right]_{i+\frac{1}{2}}^{n}-\left[\bar{\lambda}^{x} D_{x} u_{\mathrm{e}}\right]_{i-\frac{1}{2}}^{n}\right) \\
& =\frac{1}{\Delta x}\left(\left[\lambda u_{\mathrm{e}, x}\right]_{i+\frac{1}{2}}^{n}+G_{i+\frac{1}{2}}^{n} \Delta x^{2}-\left[\lambda u_{\mathrm{e}, x}\right]_{i-\frac{1}{2}}^{n}-G_{i-\frac{1}{2}}^{n} \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right)\right) \\
& =\left[D_{x} \lambda u_{\mathrm{e}, x}\right]_{i}^{n}+\left[D_{x} G\right]_{i}^{n} \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right)
\end{aligned}
$$

The reason for $\mathcal{O}\left(\Delta x^{4}\right)$ in the remainder is that there are coefficients in front of this term, say $H \Delta x^{4}$, and the subtraction and division by $\Delta x$ results in $\left[D_{x} H\right]_{i}^{n} \Delta x^{4}$

We can now use (5)-(6) to express the $D_{x}$ operator in $\left[D_{x} \lambda u_{\mathrm{e}, x}\right]_{i}^{n}$ as a derivative and a runcation error:

$$
\left[D_{x} \lambda u_{\mathrm{e}, x}\right]_{i}^{n}=\frac{\partial}{\partial x} \lambda\left(x_{i}\right) u_{\mathrm{e}, x}\left(x_{i}, t_{n}\right)+\frac{1}{24}\left(\lambda u_{\mathrm{e}, x}\right)_{x x x}\left(x_{i}, t_{n}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right)
$$

Expressions like $\left[D_{x} G\right]_{i}^{n} \Delta x^{2}$ can be treated in an identical way,

$$
\left[D_{x} G\right]_{i}^{n} \Delta x^{2}=G_{x}\left(x_{i}, t_{n}\right) \Delta x^{2}+\frac{1}{24} G_{x x x}\left(x_{i}, t_{n}\right) \Delta x^{4}+\mathcal{O}\left(\Delta x^{4}\right)
$$

There will be a number of terms with the $\Delta x^{2}$ factor. We lump these now into $\mathcal{O}\left(\Delta x^{2}\right)$. The result of the truncation error analysis of the spatial derivative is therefore summarized as

$$
\left[D_{x} \bar{\lambda}^{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n}=\frac{\partial}{\partial x} \lambda\left(x_{i}\right) u_{\mathrm{e}, x}\left(x_{i}, t_{n}\right)+\mathcal{O}\left(\Delta x^{2}\right)
$$

After having treated the $\left[D_{t} D_{t} u_{\mathrm{e}}\right]_{i}^{n}$ term as well, we achieve

$$
R_{i}^{n}=\mathcal{O}\left(\Delta x^{2}\right)+\frac{1}{12} u_{\mathrm{e}, t t t t}\left(x_{i}, t_{n}\right) \Delta t^{2}
$$

The main conclusion is that the scheme is of second-order in time and space also in this variable coefficient case. The key ingredients for second order are the centered differences and the arithmetic mean for $\lambda$ : all those building blocks feature second-order accuracy.

### 5.4 1D wave equation on a staggered mesh

### 5.5 Linear wave equation in $2 \mathrm{D} / 3 \mathrm{D}$

The two-dimensional extension of (76) takes the form

$$
\begin{equation*}
\frac{\partial^{2} u}{\partial t^{2}}=c^{2}\left(\frac{\partial^{2} u}{\partial x^{2}}+\frac{\partial^{2} u}{\partial y^{2}}\right)+f(x, y, t), \quad(x, y) \in(0, L) \times(0, H), t \in(0, T], \tag{87}
\end{equation*}
$$

where now $c(x, y)$ is the constant wave velocity of the physical medium $[0, L] \times[0, H]$. In the compact notation, the PDE (87) can be written

$$
\begin{equation*}
u_{t t}=c^{2}\left(u_{x x}+u_{y y}\right)+f(x, y, t), \quad(x, y) \in(0, L) \times(0, H), t \in(0, T] \tag{88}
\end{equation*}
$$

in 2D, while the 3D version reads

$$
\begin{equation*}
u_{t t}=c^{2}\left(u_{x x}+u_{y y}+u_{z z}\right)+f(x, y, z, t), \tag{89}
\end{equation*}
$$

for $(x, y, z) \in(0, L) \times(0, H) \times(0, B)$ and $t \in(0, T]$.

Approximating the second-order derivatives by the standard formulas (17)-(18) yields the scheme

$$
\begin{equation*}
\left[D_{t} D_{t} u=c^{2}\left(D_{x} D_{x} u+D_{y} D_{y} u\right)+f\right]_{i, j, k}^{n} . \tag{90}
\end{equation*}
$$

The truncation error is found from

$$
\begin{equation*}
\left[D_{t} D_{t} u_{\mathrm{e}}=c^{2}\left(D_{x} D_{x} u_{\mathrm{e}}+D_{y} D_{y} u_{\mathrm{e}}\right)+f+R\right]^{n} . \tag{91}
\end{equation*}
$$

The calculations from the 1D case can be repeated to the terms in the $y$ and $z$ directions Collecting terms that fulfill the PDE, we end up with

$$
\begin{align*}
R_{i, j, k}^{n}= & {\left[\frac{1}{12} u_{\mathrm{e}, t t t t} \Delta t^{2}-c^{2} \frac{1}{12}\left(u_{\mathrm{e}, x x x x} \Delta x^{2}+u_{\mathrm{e}, y y y y} \Delta x^{2}+u_{\mathrm{e}, z z z z} \Delta z^{2}\right)\right]_{i, j, k}^{n}+}  \tag{92}\\
& \mathcal{O}\left(\Delta t^{4}, \Delta x^{4}, \Delta y^{4}, \Delta z^{4}\right) .
\end{align*}
$$

## 6 Truncation errors in diffusion equations

### 6.1 Linear diffusion equation in 1D

The standard, linear, 1D diffusion equation takes the form

$$
\begin{equation*}
\frac{\partial u}{\partial t}=\alpha \frac{\partial^{2} u}{\partial x^{2}}+f(x, t), \quad x \in(0, L), t \in(0, T], \tag{93}
\end{equation*}
$$

where $\alpha>0$ is the constant diffusion coefficient. A more compact form of the diffusion equation is $u_{t}=\alpha u_{x x}+f$.
The spatial derivative in the diffusion equation, $\alpha u_{x} x$, is commonly discretized as $\left[D_{x} D_{x} u\right]_{i}^{n}$ The spatial derivative in the difusion equation, $\alpha u_{x} x$, is commonly

The Forward Euler scheme in time. Let us start with the simple Forward Euler scheme:

$$
\left[D_{t}^{+} u=\alpha D_{x} D_{x} u+f\right]^{n}
$$

The truncation error arises as the residual $R$ when inserting the exact solution $u_{\mathrm{e}}$ in the discrete equations:

$$
\left[D_{t}^{+} u_{\mathrm{e}}=\alpha D_{x} D_{x} u_{\mathrm{e}}+f+R\right]_{i}^{n} .
$$

Now, using (11)-(12) and (17)-(18), we can transform the difference operators to derivatives:

$$
\begin{aligned}
u_{\mathrm{e}, t}\left(x_{i}, t_{n}\right) & +\frac{1}{2} u_{\mathrm{e}, t t}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)=\alpha u_{\mathrm{e}, x x}\left(x_{i}, t_{n}\right)+ \\
& \frac{\alpha}{12} u_{\mathrm{e}, x x x x}\left(x_{i}, t_{n}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right)+f\left(x_{i}, t_{n}\right)+R_{i}^{n} .
\end{aligned}
$$

The terms $u_{\mathrm{e}, t}\left(x_{i}, t_{n}\right)-\alpha u_{\mathrm{e}, x x}\left(x_{i}, t_{n}\right)-f\left(x_{i}, t_{n}\right)$ vansih because $u_{\mathrm{e}}$ solves the PDE. The truncation error then becomes

$$
R_{i}^{n}=\frac{1}{2} u_{\mathrm{e}, t t}\left(t_{n}\right) \Delta t+\mathcal{O}\left(\Delta t^{2}\right)-\frac{\alpha}{12} u_{\mathrm{e}, x x x x}\left(x_{i}, t_{n}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right)
$$

The Crank-Nicolson scheme in time. The Crank-Nicolson method consists of using a centered difference for $u_{t}$ and an arithmetic average of the $u_{x} x$ term:

$$
\left[D_{t} u\right]_{i}^{n+\frac{1}{2}}=\alpha \frac{1}{2}\left(\left[D_{x} D_{x} u\right]_{i}^{n}+\left[D_{x} D_{x} u\right]_{i}^{n+1}+f_{i}^{n+\frac{1}{2}} .\right.
$$

The equation for the truncation error is

$$
\left[D_{t} u_{\mathrm{e}}\right]_{i}^{n+\frac{1}{2}}=\alpha \frac{1}{2}\left(\left[D_{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n}+\left[D_{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n+1}\right)+f_{i}^{n+\frac{1}{2}}+R_{i}^{n+\frac{1}{2}} .
$$

To find the truncation error, we start by expressing the arithmetic average in terms of values at time $t_{n+\frac{1}{2}}$. According to (21)-(22),

$$
\frac{1}{2}\left(\left[D_{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n}+\left[D_{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n+1}\right)=\left[D_{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n+\frac{1}{2}}+\frac{1}{8}\left[D_{x} D_{x} u_{\mathrm{e}, t t}\right]_{i}^{n+\frac{1}{2}} \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) .
$$

With (17)-(18) we can express the difference operator $D_{x} D_{x} u$ in terms of a derivative:

$$
\left[D_{x} D_{x} u_{\mathrm{e}}\right]_{i}^{n+\frac{1}{2}}=u_{\mathrm{e}, x x}\left(x_{i}, t_{n+\frac{1}{2}}\right)+\frac{1}{12} u_{\mathrm{e}, x x x x}\left(x_{i}, t_{n+\frac{1}{2}}\right) \Delta x^{2}+\mathcal{O}\left(\Delta x^{4}\right) .
$$

The error term from the arithmetic mean is similarly expanded,

$$
\frac{1}{8}\left[D_{x} D_{x} u_{\mathrm{e}, t t}\right]_{i}^{n+\frac{1}{2}} \Delta t^{2}=\frac{1}{8} u_{\mathrm{e}, t t x x}\left(x_{i}, t_{n+\frac{1}{2}}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{2} \Delta x^{2}\right)
$$

The time derivative is analyzed using (5)-(6):

$$
\left[D_{t} u\right]_{i}^{n+\frac{1}{2}}=u_{\mathrm{e}, t}\left(x_{i}, t_{n+\frac{1}{2}}\right)+\frac{1}{24} u_{\mathrm{e}, t t t}\left(x_{i}, t_{n+\frac{1}{2}}\right) \Delta t^{2}+\mathcal{O}\left(\Delta t^{4}\right) .
$$

Summing up all the contributions and notifying that

$$
u_{\mathrm{e}, t}\left(x_{i}, t_{n+\frac{1}{2}}\right)=\alpha u_{\mathrm{e}, x x}\left(x_{i}, t_{n+\frac{1}{2}}\right)+f\left(x_{i}, t_{n+\frac{1}{2}}\right),
$$

the truncation error is given by

$$
\begin{aligned}
R_{i}^{n+\frac{1}{2}}= & \frac{1}{8} u_{\mathrm{e}, x x}\left(x_{i}, t_{n+\frac{1}{2}}\right) \Delta t^{2}+\frac{1}{12} u_{\mathrm{e}, x x x x}\left(x_{i}, t_{n+\frac{1}{2}}\right) \Delta x^{2}+ \\
& \frac{1}{24} u_{\mathrm{e}, t t t}\left(x_{i}, t_{n+\frac{1}{2}}\right) \Delta t^{2}++\mathcal{O}\left(\Delta x^{4}\right)+\mathcal{O}\left(\Delta t^{4}\right)+\mathcal{O}\left(\Delta t^{2} \Delta x^{2}\right)
\end{aligned}
$$

6.3 A nonlinear diffusion equation in 2D

## 7 Exercises

## Exercise 1: Truncation error of a weighted mean

Derive the truncation error of the weighted mean in (19)-(20)
Hint. Expand $u_{\mathrm{e}}^{n+1}$ and $u_{\mathrm{e}}^{n}$ around $t_{n+\theta}$
Filename: trunc_weighted_mean.pdf.

## Exercise 2: Simulate the error of a weighted mean

We consider the weighted mean

$$
u_{\mathrm{e}}\left(t_{n}\right) \approx \theta u_{\mathrm{e}}^{n+1}+(1-\theta) u_{\mathrm{e}}^{n} .
$$

Choose some specific function for $u_{\mathrm{e}}(t)$ and compute the error in this approximation for a sequence of decreasing $\Delta t=t_{n+1}-t_{n}$ and for $\theta=0,0.25,0.5,0.75,1$. Assuming that the error equals $C \Delta t^{r}$, for some constants $C$ and $r$, compute $r$ for the two smallest $\Delta t$ values for each choice of and compare with the truncation error (19)-(20). Filename: trunc_theta_avg.py.

## Exercise 3: Verify a truncation error formula

Set up a numerical experiment as explained in Section 3.5 for verifying the formulas (15)-(16) Filename: trunc_backward_2level.py.

## Exercise 4: Truncation error of the Backward Euler scheme

Derive the truncation error of the Backward Euler scheme for the decay ODE $u^{\prime}=-a u$ with constant $a$. Extend the analysis to cover the variable-coefficient case $u^{\prime}=-a(t) u+b(t)$. Filename trunc_decay_BE.py.

## Exercise 5: Empirical estimation of truncation errors

Use the ideas and tools from Section 3.5 to estimate the rate of the truncation error of the Backward Euler and Crank-Nicolson schemes applied to the exponential decay model $u^{\prime}=-a u$, $u(0)=I$.

Hint. In the Backward Euler scheme, the truncation error can be estimated at mesh points Hint. $\ldots, N$, while the truncation error must be estimated at midpoints $t_{n}, n=0, N-N$ $n=1, \ldots, N$, while the truncation error must be estimated at midpoints $t_{n+\frac{1}{2}}, n=0, \ldots, N-1$
for the Crank-Nicolson scheme. The truncation_error ( $\mathrm{dt}, \mathrm{N}$ ) function to be supplied to the or the Crank-Nicolson scheme. The truncation_error (dt, $N$ ) function to be supplied to the that $\mathrm{t}[\mathrm{i}]$ is the time point corresponding to the quantities $\mathrm{R}[\mathrm{i}]$ and $\mathrm{R}_{-} a[i]$.
Filename: trunc_decay_BNCN.py.

## Exercise 6: Correction term for a Backward Euler scheme

Consider the model $u^{\prime}=-a u, u(0)=I$. Use the ideas of Section 3.6 to add a correction term to the ODE such that the Backward Euler scheme applied to the perturbed ODE problem is of second order in $\Delta t$. Find the amplification factor
Filename: trunc_decay_BE_corr.pdf

## Exercise 7: Verify the effect of correction terms

The program decay_convrate. $\mathrm{py}^{4}$ solves $u^{\prime}=-a u, u(0)=I$, by the $\theta$-rule and computes convergence rates. Copy this file and adjust $a$ in the solver function such that it incorporates correction terms. Run the program to verify that the error from the Forward and Backward Euler schemes with perturbed $a$ is $\mathcal{O}\left(\Delta t^{2}\right)$, while the error arising from the Crank-Nicolson scheme with perturbed $a$ is $\mathcal{O}\left(\Delta t^{4}\right)$. Filename: trunc_decay_corr_verify.py.

[^0]
## Exercise 8: Truncation error of the Crank-Nicolson scheme

The variable-coefficient ODE $u^{\prime}=-a(t) u+b(t)$ can be discretized in two different ways by the Crank-Nicolson scheme, depending on whether we use averages for $a$ and $b$ or compute them at the midpoint $t_{n+\frac{1}{2}}$ :

$$
\begin{align*}
{\left[D_{t} u\right.} & \left.=-a \bar{u}^{t}+b\right]^{n+\frac{1}{2}}  \tag{94}\\
{\left[D_{t} u\right.} & \left.=-a u+b^{t}\right]^{n+\frac{1}{2}}
\end{align*}
$$

Compute the truncation error in both cases. Filename: trunc_decay_CN_vc.pdf.
Exercise 9: Truncation error of $u^{\prime}=f(u, t)$
Consider the general nonlinear first-order scalar ODE

$$
u^{\prime}(t)=f(u(t), t) .
$$

Show that the truncation error in the Forward Euler scheme,

$$
\left[D_{t}^{+} u=f(u, t)\right]^{n},
$$

nd in the Backward Euler scheme,

$$
\left[D_{t}^{-} u=f(u, t)\right]^{n},
$$

both are of first order, regardless of what $f$ is.
Showing the order of the truncation error in the Crank-Nicolson scheme

$$
\left[D_{t} u=f(u, t)\right]^{n+\frac{1}{2}},
$$

is somewhat more involved: Taylor expand $u_{\mathrm{e}}^{n}, u_{\mathrm{e}}^{n+1}, f\left(u_{\mathrm{e}}^{n}, t_{n}\right)$, and $f\left(u_{\mathrm{e}}^{n+1}, t_{n+1}\right)$ around $t_{n+\frac{1}{2}}$, and use that

$$
\frac{d f}{d t}=\frac{\partial f}{\partial u} u^{\prime}+\frac{\partial f}{\partial t} .
$$

Check that the derived truncation error is consistent with previous results for the case $f(u, t)=$ -au. Filename: trunc_nonlinear_ODE.pdf

## Exercise 10: Truncation error of $\left[D_{t} D_{t} u\right]^{n}$

Derive the truncation error of the finite difference approximation (17)-(18) to the second-orde derivative. Filename: trunc_d2u.pdf.

## Exercise 11: Investigate the impact of approximating $u^{\prime}(0)$

Section 4.1 describes two ways of discretizing the initial conditon $u^{\prime}(0)=V$ for a vibration nodel $u^{\prime \prime}+\omega^{2} u=0$ : a centered difference $\left[D_{2 t} u=V\right]^{0}$ or a forward difference $\left[D_{t}^{+} u=V\right]^{0}$. he program vib_undamped.py ${ }^{5}$ solves $u^{\prime \prime}+\omega^{2} u=0$ with $\left[D_{2 t} u=0\right]^{0}$ and features a function onvergence_rates for computing the order of the error in the numerical solution. Modify thi program such that it applies the forward difference $\left[D_{t}^{+} u=0\right]^{0}$ and report how this simpler and more convenient approximation impacts the overall convergence rate of the scheme. Filename trunc_vib_ic_fw.py.

## Exercise 12: Investigate the accuracy of a simplified scheme

Consider the ODE

$$
m u^{\prime \prime}+\beta\left|u^{\prime}\right| u^{\prime}+s(u)=F(t) .
$$

The term $\left|u^{\prime}\right| u^{\prime}$ quickly gives rise to nonlinearities and complicates the scheme. Why not simply apply a backward difference to this term such that it only involves known values? That is, we propose to solve

$$
\left[m D_{t} D_{t} u+\beta\left|D_{t}^{-} u\right| D_{t}^{-} u+s(u)=F\right]^{n} .
$$

Drop the absolute value for simplicity and find the truncation error of the scheme. Perform numerical experiments with the scheme and compared with the one based on centered difference. Can you illustrate the accuracy loss visually in real computations, or is the asymptotic analysis here mainly of theoretical interest? Filename: trunc_vib_bw_damping.pdf
